SUPPLEMENT TO "THE ELECTRICIAN," NOVEMBER 2, 1894.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXXIII.

FROM MAY 4, 1894, TO OCTOBER 26, 1894.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1894.

INDEX TO "THE ELECTRICIAN."

VOL. XXXIII.

General Alphabetical Index.

Italic figures denote that the subject matter is in the "LEADING ARTICLES" or in the "EDITORIAL NOTES."

A

ABNEY, Capt. :
  Photographs of Flames, 267
Académie des Sciences (*Election of M. d'Arsonval*), 172
Accidents, (*Blackfriars*) *257*, (*Prescot*) 291, (*Leicester*) 591, (*Bournemouth*) 624, (*Bankside*) 655, (*Boston*) 684
ADDENBROOKE, G. L. :
  Some Notes on the Governing of Steam Engines, Particularly when Coupled to Dynamos, 571, 745
Advertisements, Electrically Projected, *562*
Air, Electrification of, by Subtraction of Water, Preliminary Experiments: by Lord Kelvin, Magnus Maclean, and A. Galt, 490
Alkali and Bleach by Electrolysis, The Manufacture of, 629
Alloys, (*Electrical Resistance*) 122, (*Prize*) 172, (*Copper-Zinc*) 491
Alternate-Current Electric Motor, On a Synchronous: by Prof. Galileo Ferraris, 101
Alternate-Current Electromagnets, Design and Winding of: by Prof. S. P. Thompson, 54
Alternate-Current Resonance: by E. Wilson, 516
Alternate Currents and Fuses, 685
Alternate Currents, Some Advantages of: by Prof. S. P. Thompson, 481. (*See also page 486*)
Alternating Currents in a Divided Circuit: by A. Russell, 595
Alternators—
  A Large "General Electric" Machine, 259
  Ferranti, 159
  "Leeds and London," 159
  New System of the General Electric Company, 732
  Sine-Curve Machines, *258*, *319*, *476*, 511, (*Correspondence*) 497, 528
  Stanley Two-Phase, *226*, 240
Aluminium, 172, (*Torpedo Boat*) 656, (*Price*) 712
Ambulance, An Electrical, 684
American Association for the Advancement of Science, 580
American Institute of Electrical Engineers (*Philadelphia Meeting*), 163
American Notes, *692*
Anti-Arists, *32*
APPLEYARD, ROLLO :
  On Dielectrics, 74
Arc, The Electric, Rotation of: by A. P. Trotter, 297
Arc Lighting—
  Alternate-Current Arc, *505*, *535*, 543, *590*, [Rössler and Wedding] 525, 539
  Candle Power, *172*
  Carbons, (*Krupp*) 172, 685
  "Cock" Lamp, 140
  Competitive Arc Lighters, 741
  Davy Lamp, 330
  Dynamo, A 10,000 Volt, 201
  Globe Painting, 348
  Hastings Sea Front, 272
  Jehl "Hood," for Carbons, 718
  "Manhattan" Lamp, 592
  Thomson-Houston Arc Lighter Patent, 590
  Wood Arc Lighter, 259
ARNO, RICCARDO :
  Electrostatic Rotations in Rarefied Gases, 210
Asbestos, Magnetic, 535
Atmospheric Electricity, Elster and Geitel's Researches, *411*, 427
Atmospheric Electricity, 121
Auxiliary Plant Losses in Central Stations, *382*

B

BAILY, F. G. :
  Note on the Hysteresis of Iron and Steel in a Rotating Magnetic Field, 516
Batteries (Primary)—
  Battery, A Pocket, 498
  Clark Cell [Skinner], 644
  Dry Cells, 621, 646
  Velvo-Carbon Battery, 564
Batteries (Secondary)—
  Accumulators, 748
  Accumulators, Chemical Theory of [Wade], 603, 625, 657, 688, 722
Batteries (Secondary) *Continued.*—
  Chloride, 468, 529
  Lithanode, 56
  Litigation in the United States, 611
  Manufacture in Spain, 382
  Mines, Accumulators in, 746
  Phenomena, 685
  Preparation of Solution [Sayers], 426
  Proposed Prolongation of the Faure Patent, 259
Battery, A Constant and Reliable, 655
Battery Patents, 250
BEDELL, F. (and G. S. MOLER) :
  An Optical Phase Indicator and Synchroniser, 219
Bell Magnets and Ring Magnets, Damping of, by Surrounding Copper, 331
Belt and Rope Transmission Trials, 445
Berlin Electricity Works, 74
BINSWANGER, G. :
  Electric Power, Heating and Lighting, 431
BIRKELAND, M. :
  On Magnetisation Produced by Hertzian Currents—A Magnetic Dielectric, 489
BLONDEL, A. :
  Photometric Magnitudes and Units, 633
BLONDLOT, R. :
  On the Propagation of Electromagnetic Waves in Ice and on the Dielectric Power of this Substance, 732
Board of Trade (*Supposed New Rules*) 172, (*Standardising Laboratory*) 665, 693
Boilers, (*Explosions*) 202, 740, (*Trials*) 203, (*Corrosion*) 292, (*Circulation*) *382*, 395 (*See also* articles by E. T. CARTER).
Boys, Prof. Vernon, on the Newtonian Constant of Gravitation, *171*
Brakes, Electric, *621*, [Sperry] 641, 661
Breakdowns, (*Bankside*) *683*
Brighton Motor-Alternators, *119*
Briquette Fuel, Manufacture of, 4, 623
British Association:
  Attendance at Oxford, 413, 445
  Cathode Rays, Velocity of, *475*
  Confused Terminology, *443*
  Electrical Standards Committee, Report, 541
  Electrolysis of Glass, *476*
  Gas and Electricity, Relative Cost of, *443*
  General Résumé of the Proceedings, 456
  Grants, 445
  Honorary Degrees, 445
  Lord Salisbury's Address, *411*, 429
  Papers likely to be read, *381*
  Papers Read, List of, 455. (*See also* Appendix "Scientific Societies")
  Proposed Meeting at Liverpool in 1896, 445
  Proposed Meeting at Toronto in 1897, 226
  Signalling Inductively, *443*
  Wave-Length Nomenclature, *476*
"British" Electricians, 624
BROCA, A. :
  Theoretical and Experimental Investigations on the Visual Sensations, and on Photometry, 752 (*See also* page *739*)
BRYAN, G. H. :
  Electromagnetic Induction in Plane, Cylindrical, and Spherical Current Sheets, and its Representation by Moving Fields of Images, 74
Buffalo Cataract Construction Company, 276
BURTON, Dr. C. V. :
  On the Mechanism of Electrical Conduction (Part I.), 53

C

Cambridge, (*Mathematics and Engineering*) *44*, *67*, 85, (*Engineering Laboratory*) 70, 173
CAMPBELL, ALBERT :
  On the Finding of Faults in Coils wound on Conducting Bobbins, 203
Canadian Electrical Association (*Montreal Meeting*), 383
Canal Lighting, 349
Candle Powers, 149, *172*, 568
Carbon, Atomic Weight of, *622*
CARDEW, Major P. :
  Note on the Possibility of Obtaining a Unidirectional Current to Earth from the Mains of an Alternate Current System, 298
  On the Difference of Potential that may be Established at the Surface of the Ground immediately above and at various Distances from a Buried Mass of Metal charged from a High-Pressure Electric Light Supply, 624
CARROL, J. G. :
  The Three-Wire Trolley System at Bangor (Me.), 573
CARTER, E. TREMLETT :
  Motive Power and Gearing, 36, 71, 98, 175, 293, 351, 423, 509, 593, 743
    Babcock-Wilcox Boiler, 352
    Boiler Trials, 423
    Cylinder Expansion, 743
    Draught, 36
    "Economic" Boiler, 351
    Economisers, 293
    Engine Economy, 593
    Evaporating Surface, 175
    Feed, 176
    Feed Pumps, 294
    Furnaces, 98
    Galloway Boiler, 351
    Lancashire Boiler, 294
    Locomotive Boiler, 351
    Steam Mains, 509
    Steam Space, 175
    Stoking, 71
    Water Room, 175
Cataloguing Science, *268*
Cathode Rays, On the Magnetic Deflection of: by Prof. P. Lenard, 108; by Prof. G. F. Fitzgerald, 151. (*See also page 290*)
Cathode Rays, Velocity of, *475*, [J. J. Thomson] 672
Central Station, (*Auxiliary Plant Losses*) *382*, (*Ideals*) *188*, (*Large v. Small*) *94*, (*Practice*) *359*, (*Desiderata*) *347*, (*American and German Statistics*) 275
Central Stations.
  Brighton, 123
  Burton, 156
  Ealing, 656
  German, 337
  Hampstead, 656
  Portsmouth, 156, 202
  Worcester, 669, 686, *711*
Central Station, The Whole Duty of a, *712*
Certificates, *32*
Charges for Current, 69
Circles, Areas of, 713
Civil Engineers, Institution of, (*Student's Meetings*) *93*, 95, (*Annual Meeting*) 121, (*Premiums*) 149, (*New Building*) 383, (*Roll of Members*) 654, (*Papers*) 655
Companies, Limited: by George Wreford, 495
Commutators, Ramsay's Gear, 757
COMPANIES' MEETINGS, REPORTS, DIVIDENDS, STATUTORY RETURNS, &c.
  African Direct Telegraph Company—29, 223; Stat., 503
  African Gold Recovery Company—286, 559; Div., 619; Mtg., 681
  African Trans-Continental Telegraph Company—29; Mtg., 65, 90; Stat., 197
  Akester Electro-Motor and Accumulator Company—Stat., 503
  Albert Electric Lighting Company—Stat., 197
  Aluminium Company—Div., 681; Mtg., 709
  Alwyn, L.—Stat., 91
  American River Electric Power Supply Company—255
  Andrew, J. E. H., and Co.—Stat., 409
  Anglo-American Telegraph Company—Stat., 117; Rpt., 344; Div., 345, 651; Mtg., 405
  Anglo-Portuguese Telephone Company—223
  Angus, George, and Co.—Div., 169
  Armstrong, Sir W. G., Mitchell and Co.—Div., 619
  Aurora Electric Lighting and Distribution Company—Stat., 737
  Automatic Electric Railway Signal Company—Stat., 197
  Babcock and Wilcox—Div., 559; Mtg., 619; Stat., 737
  Baily and Grundy, London—503
  Baily, Grundy and Barrett—Stat., 197
  Benham and Froud—Stat., 117
  Bickle and Co.—Stat., 737
  Birmingham Central Tramways Co.—681; Rpt., 440; Mtg., 472, 709, 737, 763
  Birmingham House-to-House Electricity Company—Stat., 117, 223
  Birmingham Mint—Div., 255
  Blackpool, St. Anne's, and Lytham Tramways Company—619
  Bolckow, Vaughan and Co.—587
  Bowen Kerbey—Stat., 223
  Brazilian Submarine Telegraph Company—Mtg., 26, 760; Stat., 145, 345; Div., 709; Rpt., 736
  British Insulated Wire Company—Stat., 255

COMPANIES' MEETINGS, &c. *(Continued)*—

British North Borneo Co.—587; Mtg., 317
British Thomson-Houston—Stat., 483
Browett, Lindley and Co.—681; Stat., 255
Brush Electrical Engineering Co.—503; Div., 619; Rpt., 651; Mtg., 673
Buenos Ayres Electric Light Company—Stat., 737
Californian Electric Power and Mining Development Syndicate—Stat., 737
California Gas, Water and Electric Light Syndicate—Stat., 65
Callender's Bitumen Telegraph and Waterproof Company—Stat., 255
Cambridge Electric Supply Company—Stat., 65
Cambridge University and Town Electric Lighting Company—255
Cape Town and Suburban Electric Lighting Syndicate—Div., 317
Central Chili Copper Company—286; Mtg., 709
Chagford and Devon Electric Light Company—Mtg., 91
Chamberlain and Hookham—Stat., 65
Charing Cross and Strand Electricity Supply Corporation—Stat., 65; Div., 473
Chatham, Rochester, and District Electric Lighting Company—Stat., 65
Chili Telephone Company—Rpt, 378; Mtg, 405; Stat. 619
Chilian Manganese Mines—286
China and Japan Telephone Company—65; Stat., 197
City and South London Railway Company—Rev., 29, 65, 91, 117, 145, 169, 197, 223, 255, 287, 317, 345, 409, 441, 473, 503, 531, 559, 587, 619, 651, 681, 709, 737, 763; Rpt., 378; Mtg., 406
City of Bath Electric Lighting and Engineering Company—Stat., 65
City of London Electric Lighting Company—223; Div., 255, 287; Rev., 317, 345, 709
City of Westminster Electrical Syndicate—Mtg., 587
Collier Audible Telephone Syndicate—Stat., 559
Commercial Cable Company—Div., 197, 559
Compagnie Française du Télégraphe de Paris à New York—441, 619; Rpt., 168, 587; Mtg., 680
Consolidated Telephone Construction and Maintenance Company—29; Mtg., 142
Corlett Electrical Engineering Company—Stat., 117
County of London and Brush Provincial Electric Lighting Company—Stat., 65, 92
Cork Tramways Company—255
Crompton and Co.—Rpt., 440; Mtg., 471, 531
Crossley Telephone Company—Stat., 65
Cuba Submarine Telegraph Company—Rev., 29, 169, 287, 409, 559, 681; Stat., 65; Rpt., 473; Mtg., 502
Cuttriss, Wallis and Co.—Stat., 403

Edison-Gower-Bell Telephone Company of Europe—Stat., 91
Edmundsons (Limited)—Rpt., 650
Electric and Automatic Engineering Company—Stat., 91
Electric and General Investment Company—Div., 169; Rpt., 196; Mtg., 253, 255; Stat., 503
Electric Construction Company—531; Rpt., 559; Mtg., 585; Stat., 763
Electric Exploitation Company—91; Stat, 763
Electric Lighting and General Development Syndicate—Stat., 441
Electric Semaphore Syndicate—531
Electric Time Distributing and Clock Company—Stat, 441
Electric Traction Company—Stat., 531
Electric Trust—Stat., 145
Electric Wiring and Fittings Company—Stat., 197
Electrical Company—Stat., 531
Electrical Power Storage Company—Mtg., 341; Stat., 531
Electricity Supply Company for Spain—197
Electricity Users' Association—Stat., 441
Electro-Chemical Company—Mtg., 196; Stat., 441
Electrophone—763
Elektricitats Aktiengesellschaft vorm. Schuckert & Co.—Div., 285
Elektricitats Aktiengesellschaft vorm. W. Lahmeyer & Co.—255
Elmore's French Copper Depositing Company—Mtg., 342
Elmore's German and Austro-Hungarian Metal Company—287
Elmore's Patent Copper Depositing Company—255; Mtg., 287
Engineering and General Contract Corporation—503, 681, 709
English Electric Carbon Company—Stat., 763
Evered and Co.—Stat., 197; Div., 651
Exchange Telegraph Company—Stat., 531
Exeter Electric Light Company—Stat., 709
Fareham Electric Light Company—Stat., 91
Field's M.P. Development Association—Stat., 587
Ford-Lloyd Manufacturing Company—Stat., 709
Foreign Pilsen Electric Light and Power Company—Stat., 91
Fowler, Lancaster and Co.—Stat., 197
French Elmore Company—255
Froggatt's Electric Lighting Company—Stat., 379
Froggatt's Inventions Syndicate—379
Gas Light and Coke Company—Mtg., 441
General Electric Company of America—619
George Moritz—Stat., 379
Globe Telegraph and Trust Company—Rpt., 378, Mtg., 407; Stat., 587; Div., 619
Great Northern Telegraph Company—Rev., 65, 169, 223, 317, 441, 473, 559, 709
Greenwood and Batley—Stat., 379
Gulcher (New) Electric Light and Power Company—Rpt., 144; Mtg., 167, 169, 197, 223, 379, 441
Halifax and Bermudas Cable Company—Rpt., 618; Stat., 763
Hampstead Electric Light and Power Company—587
"Harp" Arc Lamp Syndicate—763
Hastings and St. Leonards-on-Sea Electric Light Company—65
Head, Wrightson and Co.—Stat., 473
Hemming, T. L., and Co.—Stat., 169, 763
Henley's, W. T., Telegraph Works Company—Stat., 145, 473; Div., 681
Hobart Electric Tramway Company—Rev., 65, 223; Mtg., 254, 255; Stat., 379
Hong Kong Electric Company—Rpt., 409
Hooper's Telegraph and India-Rubber Works—169; Stat., 473
Hopcraft Furnace Company—651
House-to-House Electric Light Supply Company—Stat., 91
Hulett, D., and Co.—Stat, 763
Humphreys (Limited)—Div., 223
Immisch Electric Launch Company—Stat., 709
India-Rubber, Gutta-Percha and Telegraph Works, Company—Stat., 91, 255; Mtg., 285
Indo-European Telegraph Company—Stat., 145; Div., 763
International Electric Subway Company—Stat., 379
Internationale Elektricitats-Gesellschaft in Wien—Div., 255, 345
Ipswich Electricity Supply Company—379
Isle of Man Electric Tramway Company—Div., 737
Johannesburg Lighting Company—Stat., 169
Keighley Electrical Engineering Company—Stat., 409
Kennedy Storage Battery Company—Stat., 197
Kensington and Knightsbridge Electric Lighting Company—Div. 287, 409
Keswick Electric Company—Stat., 91
Knight and Crowther—Div., 441
Lancashire and Cheshire House-to-House Electricity Company—Stat., 91
Lancashire and Yorkshire Electric Lighting Company—Stat., 223
Liverpool Electric Supply Company—Stat., 91, 287
Liverpool Overhead Railway Company—Rpt., 406; Mtg., 472
Lisbon-Berlyn Company—Mtg., 255
London and Hampstead Battery Co.—Stat., 473
London Electric Supply Corporation—62; Stat., 197, 441
London Health Electrical Institute—Stat., 409
London Platino-Brazilian Telegraph Company—29; Stat., 145, 503
London Tramways Company—Mtg., 317
London, Walthamstow and Epping Forest Railway—589
Manchester Edison-Swan Electric Light Company—Mtg., 408; Stat., 503
Manganese Bronze and Brass Company—Div., 379
Manitoba Electric and Gas Light Company—317
Medical Battery Company—Mtg., 223
Mersey Railway Company—559
Metropolitan Electric Supply Company—117; Stat., 145, 345, 379
Mexican Gas and Electric Light Company—Stat., 91
Mildé Telephones and Electric Supply Company—681, 737
Monte Video Telephone Company—Rpt., 763
Mosley and Co.—255; Stat., 587
National Electric Supply Company—Stat., 223
National Telephone Company—197, 287; Div., 317; Rpt., 344; Mtg., 375
New Electricity Supply Company of Croydon—Stat., 587
New Zealand Electrical Syndicate—Stat., 409
Northampton Electric Light and Power Company—Stat., 91
Northern Electric Wire and Cable Manufacturing Company—Stat., 91
Norwich Electricity Company—Mtg., 29; Stat., 409
Notting Hill Electric Lighting Company—Mtg., 317
Ogmore Valley Electric Light and Power Supply Company—Stat., 223
Oriental Telephone and Electric Company—Mtg., 255, 285; Stat., 587
Orme's Electric Signal Syndicate—Stat., 223
Oswestry Electric Lighting and Power Company—223; Stat., 409; Div., 441
Otis Elevator Company—Stat., 587
Oxford Electric Company—Stat., 223
Pacific and European Telegraph Company—223
Panulcillo Copper Company—Mtg., 91
Parker, Thomas—117, 145; Stat., 503, 619
Patents (Pioneer) Syndicate—255
Phonopore Company—Mtg., 27; Stat., 145
Phosphor Bronze Company—Stat., 117
Pickup, J. H., and Co.—Stat., 409
Planet Electrical Engineering Company—Stat., 587
Portrush Electric Railway—587
Printing Telegraph and Construction Company—317
Railway Electric Reading Lamp Company—Stat., 255
Ransome, A., and Co.—Stat., 117
Ransome, Sims and Jefferies—Stat., 117
Reuter's Telegram Company—253; Stat., 409
River Plate Electricity Company—Stat., 317
Ruston, Proctor and Co.—117
St. James' and Pall Mall Electric Light Company—Div., 287, 317, 379, 737
St. Luke's Chelsea Electric Lighting Company—409
St. Nicholas Construction Company—Stat., 587
Salisbury Electric Light and Supply Company—255; Stat., 587
Salt Lake and Ogden Gas and Electric Light Company—255
Sanitas Company—Div., 379
Saxby and Farmer—Stat., 317
Saycee Electrical Syndicate—709
Scott, Ronald A.—Stat., 317
Sheffield Electric Light and Power Company—Rpt., 169; Mtg., 196; Stat., 503
Single-Wire Multiple Telephone Signal Company—Stat., 587
South African Lighting Company—Stat, 145
South Staffordshire Tramways Company—Mtg., 197
Société Française des Télégraphes Sousmarins—Mtg., 317, 680; Rpt., 587
Southampton Electric Light and Power Company—Stat., 117
South Metropolitan Gas Company—473
Spanish National Submarine Telegraph Company—Stat, 587
Statter, J. G., and Co.—Stat., 409
Steel Company of Scotland—587
Stewart, A. and J., and Clydesdale—Div., 473
Stock Exchange Notices—117, 197, 255, 317, 379, 409, 441, 473, 531
Submarine Cables Trust—Mtg., 28, 709
Swan United Electric Light Company—Mtg., 169, 195, 255, 287
Swinburne and Co.—Stat., 619
Syndicate of Electrical Engineers—Stat., 317
Telegraph Construction and Maintenance Company—Div., 317, 345; Mtg., 377
Telegraph Manufacturing Company—Mtg., 169 Stat., 345
Telephone Company of Egypt—Stat., 145
Thetford Electric Light and Power Company—Stat., 345
Thompson, Ritchie and Co.—Stat., 169
United Alkali Company—Div., 409
United River Plate Telephone Company—Rpt., 375; Mtg., 439; Stat., 619
Universal Electric Lighting Company—619
Venezuela Telephone and Electrical Appliances Company—345; Rpt., 737; Mtg., 762
Vickers, Son and Co.—Div., 473
Walsall Electrical Company—Stat., 709
Waterhouse Electro-Metric Syndicate—Stat., 223
Waterloo and City Railway Company—Mtg., 317, 440; Rpt., 341
West African Telegraph Company—Rpt., 285, 287; Mtg., 316
West Coast of America Telegraph Company—223; Rpt., 117; Mtg., 142; Stat., 345
West India and Panama Telegraph Company—Rpt., 29; Mtg., 61; Rev., 66, 118, 223, 317, 345, 441, 503, 559, 681; Stat., 345; Div., 737
Western and Brazilian Telegraph Company—Rev., 30, 66, 92, 118, 146, 169, 197, 223, 255, 287, 317, 345, 379, 409, 441, 473, 503, 531, 567, 589, 619, 651, 681, 709, 737, 763; Stat., 345; Mtg., 88; Div., 761
Western Counties Electric Light and Power Company—Stat., 619
Western Union Telegraph Company—Div., 197, 409; Rpt., 681, 763
Westinghouse Electric Company—Mtg., 651
Westminster Electric Supply Corporation—379, 737; Mtg., 761
Willans and Robinson—223
Woking Electric Supply Company—619
Yorkshire House-to-House Electricity Company—Stat., 117

COMPANIES (NEW ELECTRICAL, &c.), REGISTERED—

The following Companies have been Registered under the Limited Liability Acts during the past half-year:—

Aktiengesellschaft für Fernsprechpatente—737
American and Parisian Massage Company—316
Ariel Arc Lamp Syndicate—737
Baird, Thompson and Co.—169
Baron, F. E., and Co.—619
Barraclough, W.—169
Belcher's Patent Smoke Preventer Company—286, 316
Binns Gas and Oil Engine Company, 144
Birmingham Stamping and Tool Company—531
Boote, T. and R.—709
Bowes, Scott and Western—709
British Aluminium Company—65
British and Foreign Electric and Engineering Company—379
British Metallic Lathing Company—619
Californian Electric Power and Mining Development Syndicate—65
Canadian Mica Company—619
Capsule Battery Company—651
Carbon Syndicate—651
Central Chili Copper Company—222
Clark's Engineering and Machine Tool Company—619
Commercial Electricity Supply Company—286
Cooper, Jos., and Son—531
Coventry Electrical Engineering Company—586
Cowper Coles Galvanising Syndicate—144
Cropper, Charlton and Co.—409

Digitized by Google

COMPANIES (NEW ELECTRICAL, &c.) REGISTERED (*Continued*)–
Cropper-Minerva Machines Company 286
Cruto Incandescent Lamp Agency—169
Dalziel Bros.—286
Dawson Gas Engines' Syndicate—197
Economic Electric Speciality Company—345
Edmondson Electricity Meter Syndicate—473
Egyptian Tramways Construction Company—317
Elastic Enamel Paint Company—379
Electric Motive Power Company, 90
Electric Novelty Syndicate—254
Electrophone—169
Elieson Electrical Switch 145
Ellis, J. C. and J. S.—345
English and Colonial Electric Light Company—197
Exploitation Company—531
Eyland and Sons—254
Forum Crucible Syndicate—531
Fraser and Fraser—254
Friesland Manufacturing Company 619
Gas and Oil Engine and Dynamo Supply Company—619
Gledhill, J. and E.—254
Gowerton Foundry Company—222
Great Western Electric Light and Power Company—286
Hall Electrical Company—763
Hall, R., and Sons Bury—709
Hampstead General Electrical Fittings Company—586
Hardwick's Purine Syndicate—379
"Harp" Arc Lamp Syndicate—29
Harvey Continental Steel Company—409
Hemming and Co.—222
Herbert, Alfred—286
Hughes, Sutton and Digby—345
Immisch Electric Launch Company—90
Jones Bros. and Co., Birmingham—345
Joyner, Charles, and Co—737
Keeling, Edgar, Teale and Co.—619
"La Boite Magique"—709
Lancashire Rubber Company, 65
Lancester, William, and Co.—587
Lea, Hohrstadt and Co.—441
Lee, Arthur, and Sons—222
Liquor Register Syndicate—587
Liverpool Rubber Company—254
Llanberis Water and Gas Company—709
Llandudno Electric Supply Company—222
Loanda Gas Company—197
London United Tramways—379
London Wire Netting Company—763
Lynton and Lynmouth Electric Light Company—531
M'Eachran, Malcolm, and Co.—619
Medical Electrical Institute 737
Metallic Drawing Roll Company—91
Mills, John, and Sons 379
Non-Corroding Silver Metal Syndicate—286
Northern Engineers' Supply Company—254
Pass, C., and Son—587
Pulman, Abram, and Sons—286
Patent Enamel Company—379
Putney Electric Supply Company—286
Richards' Machine Tool Company—763
Richardson, Thomas, and Sons—286
Roberts and Co—469
Robinson and Auden, 145
Royce, F. H., and Co.—222
Scientific and General Enterprise Syndicate—587
Scott, Ronald A.—222
Shanks, A., and Sons—144
Spanish Telephone Company—345
Spencer and Co.—531
Stalybridge Foundry Company—737
Standard Wire Company—317
Station Indicator Company—619
Subventioned Railways Corporation—587
Sumner, J., and Co.—763
Tandem Smelting Syndicate—286
Taylor, E. and E.—345
Taylor, Rider and Co.—651
Telpher Cable and Cliff Railway Syndicate, 169
Wallace, E., and Co.—145
Wigston Electrical and Engineering Company—763
Wilkes Contract Company—91
Wills, W. and F.—317
Wimshurst, Hollick and Co.—286
Windermere and District Electricity Supply Company—286
Wray Electrical Engineering Company—379
Wrigley's Patents—91

Compass, Bersier Automatic Electric Steering, *258*
Competition, "Unfair," *739*
Compressed-Air Cars, 623
Condenser Discharge from a Man-of-War, 349, 564
Condensers, Silk as a Dielectric for, 302
Condenser Residual Charges, 742
Cooking, Electric, 56, *208*, 436
Copper, (*United States Output*) 172, (*Sp. Res.*) 303, (*Price*) 413
Corea, Electricity in, 445
Correspondence (*See* Appendix "Letters to the Editor")
Corrosion of Cast Iron Water Mains, 211
Cost of Electric Lighting, 740

Cost of Electrical Energy, 8, 46, (*Discussion*) 81, 131, 355, 389
CROVA, A.:
On the Degree of Incandescence of Lamps, 754
Curves of Current in Electromagnets and Transformers, A Graphical Method of Constructing: by Major R. L. Hippisley, 54
Customs Duties: Canadian, 281; Russian, 372; Swiss, 740
Cylinder Condensation, 73

D

Damping of Bell and Ring Magnets by Surrounding Copper, 331
DEARLOVE, ARTHUR:
Notes on the Anglo-American Telegraph Company's 1894 Atlantic Cable, 696
Dielectrics: by Rollo Appleyard, 75
Diffused Reflection, Photometry of: by E. Lommel 691
Diffusion of Light by Dull Surfaces: by C. Wiener, 549
Discharge of Electricity by Light: by Prof. Oliver Lodge, 352
Displacement Currents, 624
DOLIVO-DOBROWOLSKY, M. VON:
An Instrument for Determination of Phase Differences with Alternating Currents, 610
DU BOIS, H.:
On Magnetisation of Hollow or Solid Cylindrical Cores, 396
Ring Electromagnet for Producing Strong Fields, 397
DUFOUR, M.:
The Equality of the Velocities of Propagation of very short Electric Waves in Free Space and along Conductors, 485
DUNKERLEY, S.:
On the Whirling and Vibration of Shafts, 212
Dynamos, Sayers' Eighty Kilowatt, 582
Dynamo Steel, *654*
Dynamometry, 34
Dynamotors and Motor-Generators, Swinburne, 573

E

Earth, Possible Use of the, as a Means of Transmitting Intelligence, *147*
Ebert's Luminescence Lamp, 718
Eclairage Electrique, L', 591
Economy, The, of "Economies," *93*
Electric Discharge through Gases, 35
Electric Motive Power: by Albion T. Snell, 262, 323, 385, 479, 659, 687, 715
Electric Shocks, Treatment of People Suffering from, 173
"Electric" Waves, *147*
Electrical Conduction, On the Mechanism of: by Dr. C. Burton, 53
Electrical Energy, Cost of: by R. E. Crompton, 8, 46, (*Discussion*) 81, 131, 355, 389
Electrical Engineers, Institution of, (*Ten-Minutes Rule*) 65
Electrical Engineering in Germany, 648
Electrical Engineering in South Africa, 283
Electrical Trade Section, 54, 96, 149, 190, (*Election of Vice-President*) 445
Electrical Treatment of Mine Tailings, 648
Electrically Propelled Vehicles, 219
Electric Elevators, 337
Electric Light Arrears, 165
Electric Traction (*France*) 283, (*Germany*) 283, (*Russia*) 219, (*Rural*) 195, (*Japan*) 557, (*Buenos Ayres*) 706
Electricity Supply in London, *102*
Electro-Chemical Investigations, An Aid to, 563
Electro-Chemistry, (*Germany*) 201, 445, (*Austria*) 507
Electro-Chemistry, Modern Views of: by Prof. W. F. Ostwald, 235. (*See also page 259*)
Electrolysis, Notes on: by John Waddell, 177
Electrolysis of Badly-Conducting Liquids: by O. Lehmann, 205. (*See also page 195*)
Electrolytes, Thermo-electric Power of, 742, 756
Electrolytic Separation of Gold from Silver: by C. Schnabel, 327
Electromagnetic Force exerted on Armature: by Prof. John Hopkinson, 100
Electromagnetic Induction (Part I): by G. H. Bryan, 74
Electrometer, A Hydrostatic, 755
Electro-plating on a Large Scale, 536
Electrostatic Hysteresis, 391
Electrostatic Rotations in Rarefied Gases: by R. Arnò, 210
Electrotechnology, Military, A Course of, 623
Elliptically Polarised Radiation: by Prof. Oliver Lodge, 394
ELSTER, J., and GEITEL, H.:
Observations on the Gradient of Atmospheric Potential, and on the Radiation of Ultra-Violet Light from the Sun, 427
Embankment, Lighting of the, 148, 383
Energie Electrique, L', 654
Engineering as a Learned Profession, 714
Engineering Literature, Popular, 4
Engineering, Sense of Proportion in, *455*
Engineers, Manufacture of, 121
Engines—
Belliss High Speed Double-Acting, 699
Hall, 609
High Speed *v.* Slow Speed, 536
Hunting of Governed Engines, *683*, 690, [Swinburne] 526, [Addenbrooke] 571, 745
Oil Engines, (*Trials at Cambridge*) 292, (*Future of*) 535
Ransome, Sims and Jefferies' High-Speed Vertical, 182
Entropy, 259, 387
EWING, Prof. J. A.:
Magnetic Qualities of Iron, 6, 38
Exhibitions—
Antwerp, 193, 675
Bordeaux, 338
Budapest, 535
Chicago, 122, 507, 673
Derby, 87
Leipzig, 95
Luxembourg, 86
Lyons, 705, 754
Nijni Novgorod, 649
Paris (1900), 227, 338, 363
Rouen, 338
Santiago, 86
Eye, Differential Sensitiveness of, 739, [Broca] 725

F

Factories, Motors in, 163
Factory Acts, The, and Electric Lighting, 227
Fagotted Iron Bar, Corrosion of, 33
FARNHAM, I. H.:
Destructive Effect of Electrical Currents on Subterranean Metal Pipes, 16, (*Discussion*) 134
Faults, Automatic Localisation of, *68*
Faults in Coils wound on Conducting Bobbins, The Finding of: by Albert Campbell, 203
Faults, Testing for, on Incandescent Circuits: by Austin S. B. Latch, 80
Faure Patent, Proposed Extension of, 279
Feeder Patent, Edison, 590
FERRARIS, Prof. GALILEO:
A Method for the Treatment of Rotating or Alternating Vectors, with an Application to Alternate-Current Motors, 110, 129, 152, 184
On a Synchronous Alternate-Current Electric Motor, 101
Fire Alarm of the Single-Wire Multiple Telephone Signal Company, 447
Fire Pail Indicators, 336
Fires, Banked, Loss of Fuel with, 350
Fires, (*Siemens-Halske Chicago Works*) 477
FITZGERALD, Prof. G. E.:
On Herr Lenard's Experiments on the Magnetic Action of Cathode Rays, 151
On the Effect of Leakage on Wave Propagation in Telegraph Wires; or, Mr. Oliver Heaviside's Theory Explained by Analogy, 106
Flames, Photographs of: by Capt. Abney, 267
FLEMING, Dr. J. A.:
Candle-Power of Glow Lamps, 607
Cost of Glow Lamp Lighting, 565
Decorative Use of Glow Lamps, 361
Efficiencies of Glow Lamps, 537
Flying Machines, *381*
Flywheels, High-Speed, 357, 359, *444*
Franklin Institute (*Awards*), 747
French Houses of Parliament, Lighting of, 149
Frequency Transformers, 685
Furnace, Moissan Electric, 127
Fused Electrolytes and Gaseous Depolarisers: by J. W. Swan, 127
Fused Salts, Electrolysis of, *22*, 46
Fuses, Alternate-Current, 685

G

Galvanic Ring, *Punch* on, 686
Galvanometer, A New Ayrton-Mather, 661
Galvanometers, Delicate, On the Construction of: by Prof. A. Schuster, 484. (*See also page 506*)
Gas Cars, *199*, (*Chicago*) 536, (*Blackpool*) 602
Gas Charges, London, 437
Gas Consumption of Paris, 260
Gas, Explosive, Liveing Indicator, 478
Gas Lighting, Influence of Electric Lighting on, 228
Gas Mains and Electric Light Conduits, 592
Gas *v.* Electricity, (*London*) 31, (*Birmingham*) 95, (*Massachusetts*) 227, (*Relative Costs*) *443*, (*Relative Legislative Advantages*) *589*, (*Berlin*) 592, (*Biarritz*) 622, (*Launceston*) 654
Gauge, A New Wire, 754
Geissler Tube, After-Glow: by Carl Kirn, 138
German Enterprise in Turkey, 338
Gifford Prize (1896), 321
Glasgow Accounts, The, *561*
Glass, Electrolysis of, *476*
Gold from Silver, Electrolytic Separation of: by C. Schnabel, 327
Governing Electric Light Engines, *683*, 699
Graphics, 174, 564
GREATHEAD, J. H.:
Liverpool Overhead Railway, 492, 520
Guns, Operation of, by Electricity, 686

H

Hail, Production of, 292
Harmonic Analyser, *1*
Hastings, Arc Lighting at, 272
HAY, ALFRED:
On Impulsive Current-Rushes in Inductive Circuits, 229, 261, 295, 360, 393, 425
HEAP, D. T. and A. C.:
The Application of Small-Power Electric Motors, 326. (*See also page 348*)
Heat, Mechanical Equivalent of, 34, 348
Heating, Electric, (*Street Cars*) 35, (*Leonard System*) 388, (*Induced Currents*) 563
HEAVISIDE, OLIVER:
On the Transformation of Optical Wave-Surfaces by Homogeneous Strain, 113
Heaviside's Theory Explained by Analogy: by Prof. F. G. Fitzgerald, 106
HENRICI, Prof. O.:
An Elementary Theory of Planimeters, 267
Integrators, Harmonic Analysers and Integraphs, 544
HENRY, CHARLES:
Pupilometry, 331. (*See also page 320*)
Hermite Sewage Process at Ipswich, 624
Hertz, (*Biography by Ebert*) 272, 299, 332, (*Biography by Lenard*) 415
Hertz, The Work of: by Dr. Oliver Lodge, 153, 186, 204, 271, 362
Hertzian Currents, On Magnetisation produced by: by M. Birkeland, 489
Hertzian Waves (*Royal Institution*) 156, 290, 319, (*Experiments for Large Audiences*) 330, (*Magnetic Action*) 350, (*Mechanical Effects*) 357, (*Velocity of Propagation: Dufour*) 485, (*Index of Refraction: Zehnder*, 663, (*Iron Wires*) 757

Scientific Societies—Papers, &c., read before.

Académie des Sciences.
On the Degree of Incandescence of Lamps, 754 .... CROVA, A.
On the Propagation of Electromagnetic Waves in Ice and on the Dielectric Power of this Substance, 732 .... BLONDLOT, R.
The Equality of the Velocities of Propagation of Very Short Electric Waves in Free Space and along Conductors, 485 .... DUFOUR, M.

American Institute of Electrical Engineers.
An Optical Phase Indicator and Synchronizer, 210 .... BEDELL, F., and MOLER, G. S.
Destructive Effect of Electrical Currents on Subterranean Metal Pipes, 16, (*Discussion*) 134 .... FARNHAM, I. H.
The Electric Brake in Practice, 641, 661 .... SPERRY, E. A.

British Association.
Graphical Transformer, 463 .... TROTTER, A. P.
Hunting of Governed Engines, 526 .... SWINBURNE, J.
Integrators, Harmonic Analysers, and Integraphs, 544, (*Discussion*) 548 .... HENRICI, Prof. O.
Note on the Hysteresis of Iron and Steel in a Rotating Magnetic Field, 516 .... BAILY, F. G.
On the Construction of Delicate Galvanometers, 484 .... SCHUSTER, Prof. A.
On the Velocity of Cathode Rays, 672 .... THOMPSON, Prof. J. J.
Preliminary Experiments for Comparing the Discharge of a Leyden Jar through Different Branches of a Divided Channel, 491 .... KELVIN, Lord, and GALT, A.
Preliminary Experiments to find if Subtraction of Water from Air Electrifies it, 490 .... KELVIN, Lord, MACLEAN, M., and GALT, A.
Presidential Address, 429 .... SALISBURY, Lord.
Presidential Address to Section A, 417 .... RÜCKER, Prof. A. W.
Presidential Address to Section G, 450 .... KENNEDY, Prof. A. B. W.
Signalling through Space, 460 .... PREECE, W. H.
Some Advantages of Alternate Currents, 481 .... THOMPSON, Prof. S. P.
Suggested Explanation of the Secular Variation of Terrestrial Magnetism, 459 .... SCHUSTER, Prof. A.

Elektrotechnischer Verein.
Notes on the Working of the Berlin Electricity Supply, 74 .... PASSAVANT, DR.

Institution of Civil Engineers.
Electrical Equipment of the Liverpool Overhead Railway, 552, (*Discussion*) 574, 596, 637 .... PARKER, T.
Liverpool Overhead Railway, 492, 520 .... GREATHEAD, J. H., and FOX, F.
Relation of Mathematics to Engineering, 41, 78 .... HOPKINSON, Prof. J.

Institution of Electrical Engineers.
Cost of Electrical Energy, 8, 46, (*Discussion*) 81, 131, 355, 389 .... CROMPTON, R. E.
Notes on Electric Tramways in the United States and Canada, 701, 725, 751 .... WILKINSON, H. D.
The Construction of Resistances, 605, 627, 667 .... MORRIS, D. K.

Institution of Mechanical Engineers.
Presidential Address, 13, 48 .... KENNEDY, Prof. A. B. W.

Institution of Naval Architects.
The Influence of Circulation on Evaporative Efficiency of Water Tube Boilers, 395, (*Discussion*) 396 .... THORNYCROFT, J. I.

Junior Engineering Society.
The Application of Small Power Electric Motors, 325 .... HEAP, D. T. and A. C.

North-East Coast Institution of Engineers and Shipbuilders.
Presidential Address, 729 .... RICHARDSON, T.

Physical Society.
A Graphical Method of Constructing the Curves of Current in Electromagnets and Transformers, 54 .... HIPPISLEY, Major R. L.
An Elementary Theory of Planimeters, 237 .... HENRICI, Prof. O.
A New Integrating Apparatus, 267 .... SHARP, A.
Electromagnetic Induction in Plane, Cylindrical, and Spherical Current Sheets, and its Representation by Moving Fields of Images, 74 .... BRYAN, G. H.
Notes on the Behaviour of Certain Bodies in Presence of Electromagnetic Oscillations, 75 .... MINCHIN, Prof. G. M.
On Dielectrics, 75 .... APPLEYARD, R.
On the Design and Winding of Alternate-Current Electromagnets, 54 .... THOMPSON, Prof. S. P.
On the Mechanism of Electrical Conduction (Part I.), 53 .... BURTON, C. V.
Photographs of Flames, 267 .... ABNEY, Capt. W.
The Clark Cell when producing a Current, 644 .... SKINNER, S.
The Hatchet Planimeter, 267 .... HILL, F. W.

Physical Society of Erlangen.
Heinrich Hertz, 272, 299, 332 .... EBERT, Prof. H.

Reale Accademia dei Lincei.
Electrostatic Rotations in Rarefied Gases, 210 .... ARNO, R.

Royal Institution.
Work of Hertz, 153, 186, 204 .... LODGE, Prof. O. J.

Royal Society.
Magnetic Qualities of Iron, 6, 38 .... EWING, Prof. J. A., and KLAASSEN, Miss H. G.
Measurements of the Absolute Specific Resistance of Pure Electrolytic Copper, 303 .... SWAN, J. W., and RHODIN, J.
Note on the Possibility of obtaining a Unidirectional Current to Earth from the Mains of an Alternating Current System, 298 .... CARDEW, Major P.
On the Transformation of Optical Wave Surfaces by Homogeneous Strain, 113 .... HEAVISIDE, O.
On the Whirling and Vibration of Shafts, 212 .... DUNKERLEY, S.
Propagation of Magnetisation of Iron as Affected by the Electric Currents in the Iron, 237 .... HOPKINSON, Prof. J., and WILSON, E.
Rotation of the Electric Arc, 297 .... TROTTER, A. P.
Some Voltaic Combinations with Fused Electrolytes and Gaseous Depolariser, 127 .... SWAN, J. W.
The Effect of Mechanical Stress and Magnetisation on the Physical Properties of Alloys of Iron and Nickel and of Manganese Steel, 276 .... TOMLINSON, H.

Royal Society of Edinburgh.
Telegraphic Communication by Induction by means of Coils, 383 .... STEVENSON, C. A.

Verband der Elektrotechniker Deutschlands.
Modern Electrochemical Theory and its Bearing upon the Practice of the Future, 235 .... OSTWALD, Prof. W. F.
The Potential and Current Curves of Different Types of Alternators, and their Influence on the Candle-Power of Alternate-Current Arcs, 523, 539 .... ROSSLER, G., and WEDDING, W.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 833.—Vol. XXXIII. FRIDAY, MAY 4, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/*

NOTES.

Although many of the electrical exhibits at the Royal Society Conversazione on Wednesday last were not new to those who industriously attend the meetings of scientific societies, they were of very considerable interest. A number of experiments with polyphase currents were shown by Prof. S. P. Thompson, including several which were not shown at his recent Royal Institution discourse. Mr. W. W. Beaumont showed his vibro-motors and reaction balance devices, and in the same room Dr. Alexander Muirhead showed his new form of siphon recorder and curb transmitter, in connection with an artificial cable of the same capacity and conductor resistance as that which is to be laid across the Atlantic in July next. The capacity is 800 microfarads, and the resistance is 3,350 B.A. ohms. A speed of 50 words per minute is attained. Mr. Wimshurst brought models of swivels designed to connect the moorings of lightships with the shore. Each shackle contains a coil of insulated wire, and the pin of the swivel acts as a magnetic core. Mr. Crompton showed some thoroughly practical electrically-heated soldering bits, taking from 40 to 80 watts on a 100-volt circuit. Close by, Sir David Salomons had a brilliant show of very pretty vacuum tubes, showing striæ and other phenomena, which may some day prove to be of scientific interest. The Rev. F. J. Smith exhibited some ergometers, one of which was applicable as an electric governor. A Moissan furnace, Roberts-Austen pyrometer, Callendar and Griffith thermometer, and Mr. Wilde's magnetarium were among the other electrical objects.

Perhaps the most novel exhibit was that of the new harmonic analyser with a glass sphere, described at a recent meeting of the Physical Society by Prof. Henrici. The instrument, exquisitely constructed by Herr Coradi, of Zürich, is probably the most accurate and perfect integrating machine that has been made. The parts are so few, and compared with other harmonic analysers, the mechanical action is so simple, that not only its mode of working, but the result of its analysis of a curve, can be followed by sheer common sense. The operation of algebraical harmonic analysis cannot be so followed by one mathematician in a hundred. It is almost entirely blind handling of the symbols according to certain rules. To some minds this work is simply impossible, but we do not believe that this need prevent a thoroughly clear appreciation of differential and integral calculus, and of harmonic analysis. There is no algebra whatever about Prof. Henrici's machine. There is nothing but wheels, wires, rollers, a glass sphere, and several graduated scales. We look forward to the day when students who are quite unable to do the algebraical work will be allowed to study these subjects from watching the action of such machines as these. At present they are regarded as the climax of the orthodox algebraical methods, but even so fail to interest some kinds of mathematicians. Regarded from that point of view, their use is extremely limited. As educational machines they will, in proper hands, open the eyes of mechanically or geometrically-minded students to the truths of the calculus, which will perhaps still remain for them an algebraical mystery, but something more than an algebraical trick.

The past month has been a decidedly unfortunate one for electricity supply companies. On the 19th ult., Mr. Justice Kekewich decided that the City of London Electric Lighting Company ought to be mulcted for the nuisance caused by their Bankside works, although refusing to grant an injunction on the ground of the public inconvenience likely to arise from such a step. Last week Mr. Justice Stirling, in the action Wise *v.* Metropolitan Electric Supply Company, went a step further; not only were damages awarded, but an injunction was granted, though its operation was suspended for three months to give the Company time to complete their devices for overcoming the vibration trouble. The law of nuisance may, indeed, be a nuisance of a law; but as far as it relates to statutory electric lighting concerns, at any rate, lawyers are agreed that it is as plain as the proverbial pikestaff. Electric light undertakers, it appears, are authorised and impliedly required to erect generating stations *somewhere*, but not anywhere in particular; the erection and operation of a station on any site selected must not cause a nuisance at present or in future to those dwelling near. The plainness of the liability may be cold comfort to those who have rendered themselves liable; but, as an offset, there is the evident desire of the judges not to interfere more than absolutely necessary with the business of electricity supply, and as to the prevention of vibration in the future, it may be confidently asserted that the resources of civilisation have not as yet been exhausted.

In this week's issue we give in full the judgment in the important and interesting action brought against the Commercial Cable Company by Messrs. Muirhead in connection with the payment of royalties for using their American duplex

Digitized by Google

patent, No. 234,490, of 1880, which the Company alleged had lapsed by reason of the expiry of an English patent of 1876, which it was argued was an anticipation of the American one. As we have already stated, the sum involved was a large one, amounting to something like £45,000, and the elucidation of the technical points at issue required the services of Lord KELVIN, Sir FREDERICK BRAMWELL, Dr. JOHN HOPKINSON, Prof. SILVANUS THOMPSON, Dr. BOTTOMLEY, Sir HENRY MANCE, Mr. SWINBURNE, and many others, the Court being engaged in hearing the case for no less than seven days.

MR. JUSTICE KENNEDY, it will be seen, has decided against the contention of the Commercial Company that the English patent was an anticipation of the American one, and the Company's endeavour to avoid payment is therefore temporarily at all events unsuccessful. The whole case turned on the question as to whether Fig. 2 of the English patent of 1876 (see *The Electrician*, March 9th) showed substantially the same arrangement as that depicted in Fig. 3 of the American patent of 1880; whether the *continuous* adjustment of resistance was an advantage in duplex working; whether there was any point in keeping the sum of the resistances of the bridge arm constant; whether a cable man looking at Fig. 2 of 1876 would have been led to make the particular arrangement depicted in Fig. 3 of 1880. To us it seems impossible that any amount of looking at Fig. 2 of 1876 would, at any rate in 1876, have resulted in Fig. 3 of 1880, and Mr. Justice KENNEDY was of the same way of thinking. The name of MUIRHEAD is ineffaceably connected with submarine duplexing, and by the upholding of this patent substantial justice has been done.

THE electrolytic effects of traction currents are discussed in an unusually clear and instructive manner in a paper just read before the American Institute of Electrical Engineers, and reproduced in our present issue. The author, Mr. ISAIAH H. FARNHAM, of the New England Telephone and Telegraph Company, is a prophet in his own land, having been the first to connect in an indubitable manner sundry peculiar corrosion phenomena on the lead-covered cables of his Company with the leakage currents from the electric tramway system of the West End Company of Boston. Thanks in no small measure to the Board of Trade Regulations recently promulgated, we are not likely to witness in England anything approaching the state of things chronicled by Mr. FARNHAM in the first portion of his Paper; nevertheless it is instructive as showing what might have happened had there been an electric traction "boom" in this country, and no authority empowered to insist on the negative pole being put to earth, and the water mains being effectively connected to it. In this respect, indeed, Mr. FARNHAM goes beyond Board of Trade requirements. He does not rely merely on connection at the power-house, but urges that conductors should be run out to all pipes situated within what he calls "the danger territory," *i.e.*, the area within which the pipes become positive to earth. The advantages of the negative-pole-to-earth arrangement and of this additional precaution are strikingly shown in the three maps giving the electrical condition of underground Boston, firstly, with positive pole to earth and no effective connection to water and other pipes; secondly, with negative pole to earth; thirdly, with negative pole to earth, plus auxiliary conductors.

THE experiments made and facts adduced by Mr. FARNHAM, which appear to point to the possibility of serious electrolysis where there is only a minute difference of potential between pipe and earth, and to the existence of considerable electrical resistance at the joints of water pipes, require, as the daily papers say, "to be received with all reserve." The "non-conducting screen," which at one time found no little favour in high quarters, does not seem to have successfully resisted electrolytic contagion at Boston, telephone cables "painted with asphalt, taped, painted again, and finally covered again with a heavy braiding also saturated with asphalt," being badly corroded.

THE advent of May brings, among other annual institutions, the time-honoured "May exams." of the Science and Art Department, and thousands of young people, whom newspapers delight to call "embryo electricians," are preparing themselves in various ways to "sit for magnetism and electricity." Of these various ways there are two which are worthy of especial condemnation; they are, grinding and cramming. Indeed, so much are these recognised as specifics for a "pass" that the science student has long been heard to sing the paraphrase doggerel: "March grinds or April crams will get you through the May exams." Three classes of people are to blame for this melancholy state of affairs. Firstly, the Examining Department is to blame for perpetuating an antiquated, not to say fossilised, syllabus of examination, with its ridiculously unscientific division under the three heads of "magnetism, frictional electricity, and voltaic electricity," and its perpetuation in almost unvarying form of a host of "stock questions." Secondly, the instructors are at fault; and by instructors we mean both oral teachers and the authors and publishers of cram-books. During April and the early part of May the rush for printed "back papers," and pamphlets giving typical answers to selected stock questions, is simply phenomenal; while, in the vast majority of cases, the teacher devotes the last few lectures to a vigorous grinding up of his class in these back papers. Thirdly, the so-called student is to blame for prostituting his studies to a mere certificate, and for aiming at a tangible show of knowledge, in the shape of a piece of cardboard, instead of trying to fill his mind with well arranged useful knowledge that he can be sure of throughout his life.

Blake v. Pulver Transmitters.—The Christiania Telephone Company is adopting the Pulver microphone in place of the Blake. No less than 615 of the latter were replaced last year.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	Oct. 25th, 1893.
Bissao-Bolama	Nov. 24th ,,
Brest-St. Pierre (P.Q. Co.)	Mar. 29th, 1894.

Berlin Overhead Railway.—The scheme has received the consent of the German Emperor, and the work is to be begun immediately. The double line is to have a three-minute service.

Digitized by Google

The Board of Trade Electric Traction Regulations.—The electric traction regulations recently issued by the Board of Trade are described in a French contemporary as protective clauses submitted to the Minister of Commerce by a special committee appointed by the House of Commons.

Extension of the Liverpool Overhead Railway.—An extension of the Liverpool electrical overhead railway to Seaforth was inaugurated on Monday, more than a thousand passengers being booked up to noon. This extension makes the overhead railway six miles long.

Institution of Electrical Engineers.—The annual conversazione of the Institution will take place on Thursday, May 31st, and will be held, as before, in the galleries of the Royal Institute of Painters in Water Colours. The cards of invitation will be issued towards the end of this week.

Institution of Civil Engineers.—It was announced at the meeting of this Institution on Tuesday last, that Mr. James Swinburne had been transferred to the class of member. It was further announced that Mr. David Cook had been elected to the class of member; also that Mr. J. E. Baron had been elected as associate-member.

Interurban Telephony in France.—The Chambers of Commerce concerned have decided to repeat their offer to advance the sum of £3,680 to the State on the condition that a third telephone trunk line, to be devoted exclusively to main-line communications, be erected between Paris and Havre.

Glasgow and West of Scotland Technical College.—The Edinburgh University Court, at their last meeting, decided to recognise the day lectures and laboratory courses given by Prof. Andrew Jamieson at the Glasgow and West of Scotland Technical College as qualifying *pro tanto* for their degree of B.Sc., in engineering.

New Lamps for Old.—Messrs. Fleischhacker and Möhrle, of Pasing, near Munich, have introduced a method of repairing worn-out or blackened glow lamps, which is said to be perfectly successful. The saving on the price of new lamps is from 30 to 40 per cent., even at the present excessively low prices ruling in Germany.

Another Electro-Chemical Journal.—In addition to the *Electro-Chemische Zeitschrift*, referred to last week, we learn that the first number of still another journal of this kind has just seen the light. The new journal is called *Die Zeitschrift für Electrotechnik und Electrochemie*, and is edited by Herr Arthur Wilke, of Hanover, and Dr. W. Borchers, of Duisberg. The publishers are Messrs. W. Knapp, of Halle.

Electrical Exhibition at Derby.—An electrical exhibition will be opened at the Mechanics' Institute, Derby, on the 14th inst. by the Mayor. Demonstrations will be given in electrical cooking, heating, &c. In connection with the opening, Sir Frederick Bramwell will lecture on the subject of electricity. The electrical power in connection with the exhibition will be supplied from the borough electric lighting station.

Proposed Underground Railway in Budapest.—The municipal engineering department of Budapest has sanctioned the construction of an underground electric railway from the Gisela Platz under the Andrassy-strasse to the Stadt Wäldchen. The proposed capital is about £300,000. When this project is realised Budapest will be the first town to follow the example of London in the utilisation of this method of traffic.

Electric Traction at Barmen.—A somewhat unusual step has just been taken by the municipal authorities of Barmen. It appears that in the concession granted to the Elberfeld-Barmen Horse Tramways Company, a proviso was made that the Company should adopt any improvement which might offer itself in connection with tramways. The municipal authorities have therefore just decided that the Company must convert the tramways into electric lines.

Royal Institution.—At the annual meeting of this Institution on Tuesday, May 1st, the annual report of the Committee of Visitors for the year 1893, was read and adopted. The real and funded property now amounts to above £102,000. Sixty-two new members were elected in 1893. The books and pamphlets presented in 1893 amounted to about 250 volumes, making, with 584 volumes (including periodicals bound) purchased by the managers, a total of 834 volumes added to the library in the year.

The Varley Testimonial.—We have received a lengthy communication from Mr. S. A. Varley expressing his deep obligation to the members of the testimonial committee for having so gracefully recognised his services to applied science in the circular they issued on the formation of the committee, and returning his sincere thanks to all those who have subscribed to the testimonial fund. As Mr. Varley's letter will no doubt appear in full in the columns of our contemporaries, our inability to find room for it this week will not prevent it being made known.

Aldin v. Latimer Clark, Muirhead and Co.—On Wednesday Mr. Justice Stirling gave another decision adversely affecting an electric light undertaking. This was in the action brought by Mr. Aldin, timber merchant, of Richmond, against Latimer Clark, Muirhead and Co., for endangering his timber-yard and preventing free access of air to it by the erection and working of a central lighting station. The judge decided that injury had been done, but not sufficient to warrant an injunction, and ordered an inquiry as to damages. A fuller report of this action will appear in our next issue.

A Society of Electro-Chemistry in Germany.—The application of electricity to chemistry has made such progress in Germany that the formation of a German electro-chemical society is but a natural consequence. A meeting of the leading electro chemists of Germany was held at Cassel a few days ago, when the formation of such a society, with head-quarters at Berlin, was decided upon. At the meeting a council was elected, and this includes such well-known names as Ostwald, Wilke, Classen, Kraut, Bottinger, Vogel, Rathenau, &c. The object of the society is in the advancement of both the theory and practice of electro-chemistry. The first annual meeting is to be held in Berlin in October next.

Obituary.—The death is announced, at the age of 64, of Dr. Karl Eduard Zetzsche, the well-known Continental telegraph engineer. In 1856 Dr. Zetzsche took employment in the Austrian Telegraph Service. In 1858 he went to Chemnitz, where he became teacher of mathematics and mechanics at the Royal Technical High School, and in 1876 he accepted the chair of Professor of Telegraphy at the Polytechnic School in Dresden. In 1880 he went to Berlin, and became editor of the *Electrotechnische Zeitschrift* (1880-1886) and telegraph engineer to the German Postal Service (1880-1887). Dr. Zetzsche published several books on geometry, trigonometry, and telegraphy, most of them having had several editions.

Epping Forest and Walthamstow Electric Railway.—This Bill came on Wednesday before a Committee of the House of Commons, presided over by Sir J. Kennaway, and after considering the proposals of the promoters for running workmen's trains at fares of a penny for three miles, as against a penny for the whole distance, which the London County Council ask, they deferred their decision upon this point. Yesterday, the Committee decided that the Company should run workmen's trains till eight in the morning, the fare being one penny for a distance of nine miles, the Board of Trade to judge as to sufficiency of accommodation. The promoters intimated that in consequence of these onerous terms they might possibly withdraw the Bill.

Budapest.—The electric lighting works erected in Budapest by the Elektrizitäts Aktiengsellschaft, formerly Schuckert and Co., notwithstanding the competition of a supply station erected by Messrs. Ganz and Co., have been a pronounced success. The station originally planned was intended to supply 12,000 lights; but after scarcely nine months working nearly 17,000 lamps have been connected to the mains, and there is a possibility of another 37,000 being added. The result of this is that it has been decided to raise the capital of the Company from three million to five million crowns, and to carry out immediate extensions involving an expenditure of £50,000. The extension works are to be carried out by the original contractors on the same system, viz, the alternate-current-continuous-current-accumulator system.

The Post Office and the Telephones.—In the House of Commons on Monday last Sir J. Fergusson asked the Postmaster-General whether the agreement with the National Telephone Company had been completed or had made further progress? Mr. Arnold Morley stated that considerable progress had been made with the agreement, and within the last few weeks the points of difference between the Telephone Company and the Post Office had been brought within such narrow compass that he was led to believe that it might be possible to lay the agreement on the table of the House very shortly. Mr. Labouchere asked whether the agreement had not been delayed for nearly two years, and whether the effect was not to give the Telephone Company practically a monopoly as against the municipalities who wished to improve the telephone service of their towns? The Postmaster-General did not think the position of the municipalities had been prejudiced.

Telegraphy and the Recent Religious Riots in India.—The India Office has laid before Parliament a number of reports from officers in Burma, Bombay, and certain districts of the North-Western Provinces and Oude relating to the recent conflicts between Hindus and Mahomedans. Amongst the causes of the greater frequency of these conflicts in recent years the Government of India mention the greater frequency of communication and the interchange of news by post and telegraph between different parts of the country, so that the news of a riot is known all over India, and controversies arise and hostility is engendered even in districts where harmony has hitherto prevailed between the two religions, and the example set in some distant towns may thus be followed in a dozen other places where the people, but for the suggestion afforded by the example and the manner in which it is discussed, would have continued to live in mutual amity.

Telephonic Communication in Germany.—A new telephone line has just been completed and put in operation between Bingen and Mannheim. A long-distance line is also to be established to give communication between Munich, Leipzig, Berlin, and Hamburg. Some new regulations have just been issued by the German Postal authorities regarding the use of the public telephone call-offices, which are not calculated to foster or encourage the use of such means of communication. Hitherto it has only been necessary to pay the ordinary fee to an attendant on entering the telephone box; but the new regulations provide that a form must be filled up giving the office and number of the person with whom it is desired to hold communication, and also at the foot the name of the person making the call, then a postage stamp has to be purchased and affixed to the form. The form has then to be checked by the clerk, and an entry in a book made before the applicant is allowed to enter the telephone box. One advantage of the public telephone call-office system has been the despatch by which one could obtain communication, which advantage will be materially reduced under the new arrangement.

Popular Engineering Literature.—"Since the advent of several popular professional magazines, and the growth of the demands for popular scientific and engineering writing, there has been a vast amount of pseudo-scientific rubbish unloaded on the unsuspecting public," says the *Electrical World*. "As the average reader of these articles is unable to comprehend the real scientific principles at stake, it is therefore thought necessary to select the merely striking and curious points for their delectation. These are then enlarged upon to an alarming extent, and all sorts of speculations added, until the impression is left upon the minds of the readers that scientists and engineers must be a poor lot indeed to be unable to realise some of the promises thus glibly held out by these writers—who, by the way, are almost always unknown in the scientific or professional circles they purport to represent. It is this class who have made a shibboleth of the phrase 'Electricity is yet in its infancy,' who picture the modern ocean ship propelled by electricity crossing the ocean in a day, and who, after harping upon the use of electricity for trunk railways, have recently substituted electric air navigation as being less tame. One of their favourite themes is the appalling inefficiency of the steam-engine. Elaborate calculations are made to show that the steam-engine is a woefully inefficient machine, and the implication conveyed that steam engineers are a sorry lot not to apply a remedy. While it is true that from a thermodynamic standpoint the steam-engine is inefficient, this follows from a law of nature and not through the neglect of man. Another subject that has a great attraction for these gentlemen is the generation of electricity from water power. The energy of water, they argue, unlike that of coal, is free of cost, and the efficiency of the turbine is eight to ten times as great as that of the steam-engine. With these data to start with they revel in predictions; all domestic operations are to be carried on by electricity, and the farmer would sow, harvest, market and even assist the chemical growth of crops by electricity, and man would become a mere presser of electric buttons."

The Manufacture of Briquette Fuel.—At the meeting of the Institution of Civil Engineers on Tuesday, May 1st, a Paper was read on "The Manufacture of Briquette Fuel," by Mr. William Colquhoun. The Paper contained a description of the various English and Continental methods of agglomerating slack coal, which had now become an important and increasing industry, and opened up an outlet for large quantities of small coal hitherto lost on the pit-bank or in the workings. Various agglomerating agents were detailed and their local advantages discussed; the characteristics of good pitch derived from coal-tar rendered that agent, however, in every way the most suitable. By the use of from 8 to 9 per cent. of pitch, slack coal might be agglomerated into a form eminently suitable for storage purposes, waterproof, incapable of deterioration on exposure, of cohesion greater than the large coal from which it was derived, and, finally, having calorific qualities nearly equal to large coal. In support of the latter contention, the author cited the results of three experiments with English briquettes which gave 8·41lb., 8·77lb. and 8·99lb. respectively, as the weight of water evaporated from and at 212°F. per pound of fuel. The average evaporative power of several of the best Welsh steam-coals was 9·33lb. Careful experiments made by Mr. Marié on the Paris, Lyons, and Mediterranean Railway gave as corresponding figures for three descriptions of French briquettes, 8·88lb., 9·15lb. and 8·68lb. respectively. The mechanical preparation of the coal used in briquette manufacture, received more attention on the Continent than in this country, particularly in regard to the washing and subsequent drying of the slack. These operations were necessary in order to render the poorer coals serviceable for the manufacture. The draining and drying appliances in use were described, particularly those of Jacoby, of the Molière Collieries, and of Biétrix, the latter being described in detail and instances given of the working cost. The coal and pitch were intimately intermixed by two methods, known respectively as the melted- and dry-pitch processes, the pitch by the former being melted (sometimes with additions of common tar) prior to its addition to the coal, and by the latter being ground up with the coal in a dry state. Several examples were given of the procedure in each case. In both instances the mixture of coal and pitch was subjected to the action of heat until each particle of coal was covered with a film of melted pitch and so rendered fit for compression into blocks. In this state the mixture or paste contained from 3 to 5 per cent. of water in order to facilitate the sliding of the particles of coal one on the other during compression. The machines for compressing the paste were roughly divided into three classes, irrespective of the nature of the power employed. These classes were: First, single-compression machines, illustrated by detailed descriptions of the Mazeline, Stevens, and Dupuy presses; secondly, machines compressing on both sides of the briquette, such as those of Middleton, Biétrix, and Veillon; thirdly, machines acting by the tangential pressure of rolls, like that of Fouquemberg, and those of the sausage-machine type such as the Bourriez press. Briquettes hot from the press had an inconsiderable cohesion, and had to be treated with care in stacking and loading, and arrangements made to keep down the cost of labour. Costs were given of making briquettes in works in England, in the North of France, and in Belgium. Instances were cited of the suitability of the same process for the agglomeration of charcoal-dust, sawdust, coke-breeze, friable iron-ores, and cement. An appendix gave the annual production of briquettes in various countries.

MEASURING COEFFICIENTS OF INDUCTION.

BY ALEXANDER RUSSELL, M.A.

The following methods of measuring coefficients of self and mutual induction are very convenient in practice, as they do not necessitate a rearrangement of the apparatus when measuring the two coefficients. The first method requires a condenser, in addition to the ordinary apparatus for measuring resistance, and is capable of giving very accurate results. The second method is not quite so accurate, as we make the assumption that the alternating currents follow the harmonic law; still, as this method only requires an ordinary voltmeter and ammeter suitable for use with alternating currents, it is often very useful. For example, with a Cardew voltmeter and a Siemens dynamometer, and using the current supplied by the

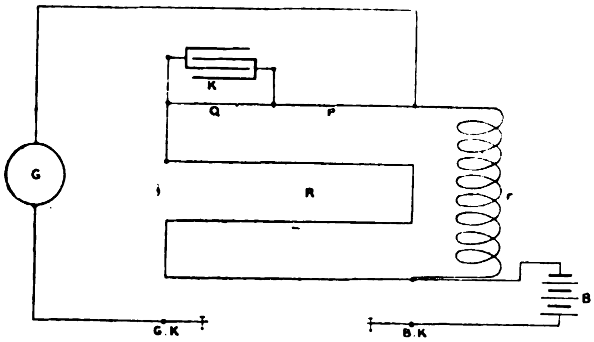

Fig. 1.—Diagram of Connections for Measuring Coefficients of Induction.

London Electric Supply Corporation, the results obtained for the coefficients of self-induction of various coils experimented on were well within 2 per cent. of their real value.

1. The apparatus required for the first method is a Wheatstone's Bridge, a mirror galvanometer, and a condenser (preferably a sub-divided one). This method can be employed when the apparatus is fitted up permanently for measuring resistance without disarranging the connections.

In Fig. 1, a Post Office box is shown, r is the inductive coil whose coefficient is to be measured, G the galvanometer, Q, P, and R the resistances of the various arms of the bridge, and K a condenser (unconnected at first).

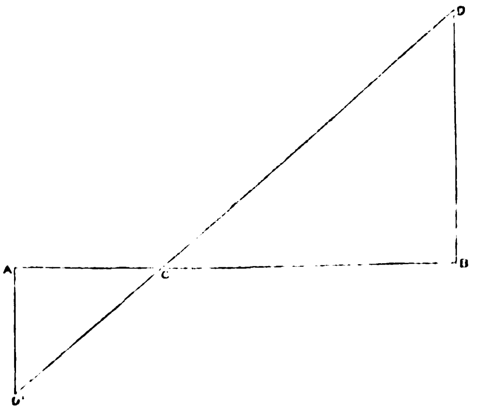

Fig. 2.

Measure the resistance of the coil r in the ordinary way, putting down the battery key before the galvanometer key, when there is a balance

$$r = \frac{P}{Q} R.$$

Now, if we put down the galvanometer key, and then the battery key, there will be a sudden throw or "kick" of the galvanometer needle, causing the spot of light to give a momentary swing to one side, and then coming back to zero. If we raise the battery key, keeping the galvanometer key down, there will be an equal kick in the reverse direction. These effects are due to the self-induction of the coil r upsetting the balance until the current in r attains its steady value, the E.M.F. of self-induction being only brought into play when the current is growing or diminishing.

Now, if we shunt the resistance Q with the condenser K, and perform the same operations as before, the kick will be much smaller, or may even be in the reverse direction.

Suppose that when K is K_1 we get a kick of d_1 divisions to the right, and that when K is K_2 we get a kick of d_2 divisions to the left. Then, to find the value of K that will annul the kick, make (Fig. 2) the line A B equal to $K_2 - K_1$ in any convenient scale. Draw A D_1, B D_2 at right angles to A B, and make A $D_1 = d_1$ and B $D_2 = d_2$. Let $D_1 D_2$ cut A B in C. Then, when $K = K_1 + A C$ there will be no kick when we put the galvanometer key down before the battery key. When this is the case, we can show that if L be the coefficient of self-induction of the coil r, then

$$L = K Q r \times 10^{-6} \text{ henrys},$$

where K is in microfarads and Q and r in ohms.

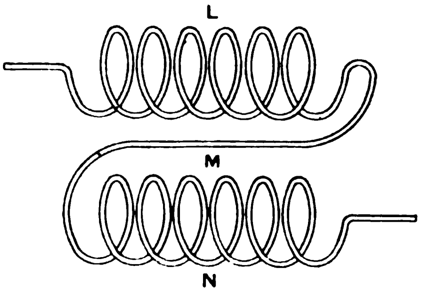

Fig. 3.—Effective Self Induction = L + N + 2 M.

We can also employ this method to measure the coefficient of mutual induction between two coils. Let L and N be the coefficients of self-induction of the two coils, and M the required coefficient of mutual induction. Then, if we connect the two coils in series, as in Fig. 3, the mutual inductive E.M.F. on each coil acts in the same way as the self-inductive E.M.F.

Hence, if L′ be the coefficient of self-induction of the two coils connected in this way, and measured as above, we obviously have

$$L' = L + N + 2 M.$$

Similarly, if L″ be the coefficient of self-induction of the two coils connected, as in Fig. 4,

$$L'' = L + N - 2 M.$$

Therefore $$M = \tfrac{1}{4} (L' - L'').$$

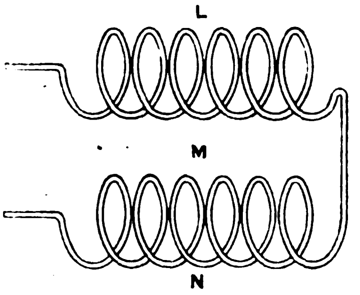

Fig. 4.—Effective Self Induction = L + N - 2 M.

Hence the apparatus set up as in Fig. 1 can be used for measuring resistance, self-induction, and mutual induction.

It is sometimes useful to connect the two coils in parallel, and then to measure the apparent coefficient of self-induction. If we find L_1 and L_2, as formerly, then in this case,

$$\left. \begin{aligned} L_1 &= L \left(\frac{S}{R+S} \right)^2 + N \left(\frac{R}{R+S} \right)^2 + 2 M \frac{S R}{(S+R)^2} \\ L_2 &= L \left(\frac{S}{R+S} \right)^2 + N \left(\frac{R}{R+S} \right)^2 - 2 M \frac{S R}{(S+R)^2} \end{aligned} \right\} \quad (1)$$

Hence $M = \frac{(S+R)^2}{4 S R} (L_1 - L_2)$; where R and S are the resistance of the two coils respectively.

Digitized by Google

Putting $M = 0$ in formulæ (1), we get the case when the mutual induction can be neglected,

$$L_3 = L\left(\frac{S}{R+S}\right)^2 + N\left(\frac{R}{R+S}\right)^2.$$

Putting, in addition, $N = 0$, we find that shunting an inductive coil R by a non-inductive coil S, diminishes its effective coefficient of self-induction in the ratio of S^2 to $(R+S)^2$—a well-known result.

Those who are acquainted with the theory of alternating currents can prove the formulæ (1) from the general algebraical expression for the equivalent self-induction of a branched circuit by putting the frequency = 0.

This method gives the correct values for the coefficients, even when the coils are wound on brass cores, or if there are any closed circuits near them.

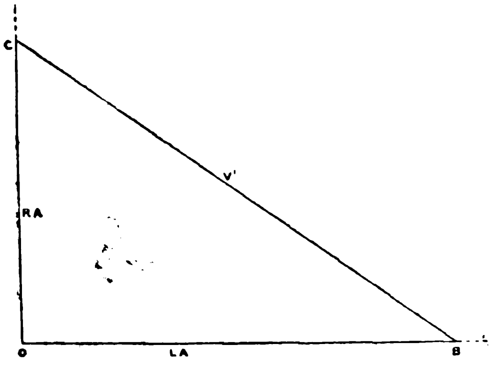

Fig. 5.

2. The method with alternating currents is as follows:— Place the coil in an alternating-current circuit. Let the current through it be A amperes, and let the potential difference between its terminals be V' volts. When placed in a direct current circuit, let the potential difference be V when the current is A. Then the following construction to find L can be proved at once from the formula for impedance. Draw (Fig. 5) O C and O D at right angles to one another. Make O C = V, with centre C and radius = V' describe a circle, cutting O D in B. Then the length of O B divided by $2\pi n A$ where n is the frequency gives the magnitude of L in henrys.

Again, for mutual induction, let the coils be connected as in Figs. 3 and 4. Let V' be the potential difference between the terminals in the first case, and V'' be the potential

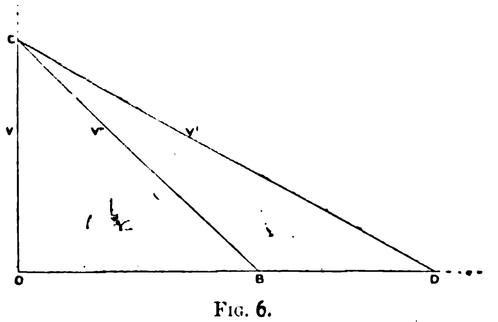

Fig. 6.

$OC = V = RA.$ $OB = 2\pi n L''A.$ $OD = 2\pi n L'A.$ $BD = 8\pi n MA.$

difference in the second case when the same current A is flowing through it, and let V be the potential difference with a direct current A. Then, using the same construction as before, make C D = V' and d C B = V'' (Fig. 6). The length of B D divided by $8\pi n A$ will give the coefficient of mutual induction between the coils.

This method fails to measure the coefficient of mutual induction between two coils, when this coefficient is very small compared to the sum of the coefficients of self-induction. For example, in a Siemens' wattmeter, which measures up to 2,400 watts, the coefficient of self-induction of the volt coil was greater than half a henry, while the coefficient of mutual induction between the coils was only 20 microhenrys, when the pointer of the ampere coil was at zero. It also fails if there are any closed circuits or masses of non-magnetic metal near the coils, a consideration which does not affect the first method.

Although coefficients of self and mutual induction can be measured easily practically, it is very difficult to calculate them from the geometrical dimensions of the coils. In fact, it is only in a very limited number of cases that they can be found, and even in these cases the length of the formulæ are prohibitive to all but the most expert calculators. As a rule also, the formulæ given for them in pocket-books (when correct) are only rough approximations, and unless we know exactly where the approximation comes in, it is never safe to use them.

MAGNETIC QUALITIES OF IRON.*

BY J. A. EWING, F.R.S., AND MISS HELEN G. KLAASSEN.

(Continued from page 715, Vol. XXXII.)

Fig. 25 gives the curves drawn by the magnetic curve tracer in a series of tests of a pair of bars built up of soft thin sheet iron. Four cycles are shown, the magnetising current having had as extreme values three, two, one and one-half amperes

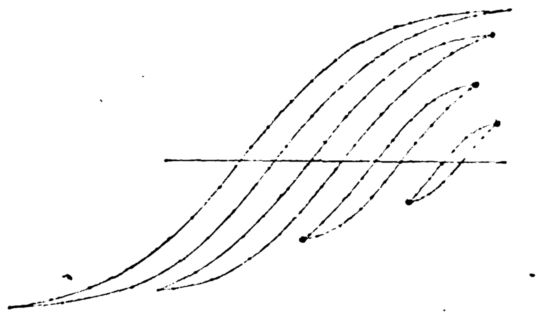

Fig. 25.—Cycle Magnetisation of Soft Iron, shown by the Magnetic Curve Tracer.

respectively. The zero was shifted a little before each cycle to separate the curves. Here the changes of current took place slowly, a pause being made at each of the marked points to allow the position of the reflected spot of light to be noted. The curves are sheared over to the right

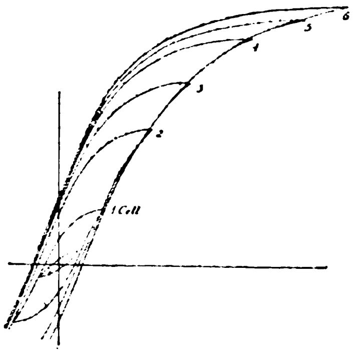

Fig. 26.—Cyclic Magnetisation of Soft Iron, shown by the Magnetic Curve Tracer.

in consequence of the gap in the magnetic circuit under test. The areas of these curves, which are not affected by this shearing, when plotted in relation to B are found to lie on a smooth curve of the type drawn in Fig. 21.

Fig. 26 is another test of the same class, made with a different curve tracer and with other iron. Here the successive cycles are shown in their natural relation to one another, without change of zero, and it will be seen that they show well a feature which was referred to in the ballistic tests, namely the projection of the extremities of each cyclic curve over the rising limb of the cycle next above it. Many other examples of curve-tracer tests might be cited as confirming this observation.

* Abstract of Paper read before the Royal Society.

Digitized by Google

Fig. 27 is closely related to Fig. 26. It shows a group of curves taken in immediate succession to the group of Fig. 26, the iron, the instrument, and the condition of the experiment being in every way the same, except that in Fig. 27 the cycles

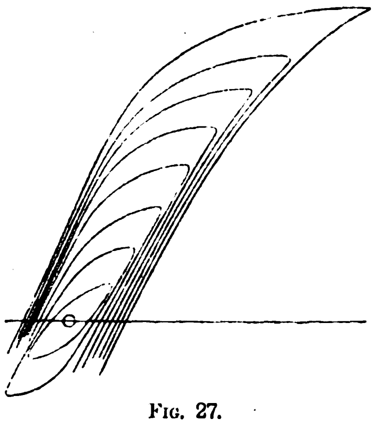

FIG. 27.

were gone through comparatively fast—at the rate of 3½ cycles per second—whereas in Fig. 26 the process was quite slow. The rounded corners and increased wideness of these curves should be noticed. Their increased area shows that more work

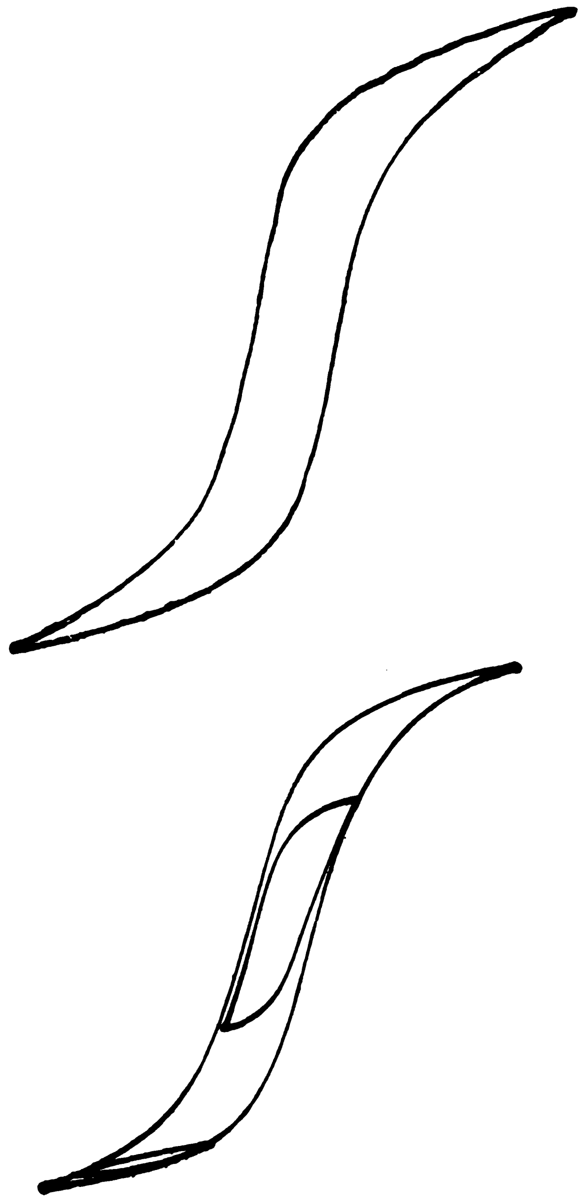

FIG. 28.

is here being done on the iron, the effect probably—at least in great part—of Foucault currents. The main portion of the magnetic circuit consisted, in this instance, of well laminated metal, but thick solid pole pieces were used

The curves of Fig. 27 were recorded by marking with a pencil the luminous line described upon the screen in the periodic repetition of each cycle. In Fig. 28, where the results of a group of tests with a different instrument are shown, the curves were automatically recorded by allowing the spot of light to fall on a sensitive plate.* In all except the last figure in this group each cycle was gone through in about half a second—the commutator being driven uniformly by means of a small electric motor—and the exposure lasted during some 20 to 30 cycles. The curves, therefore, give good evidence of

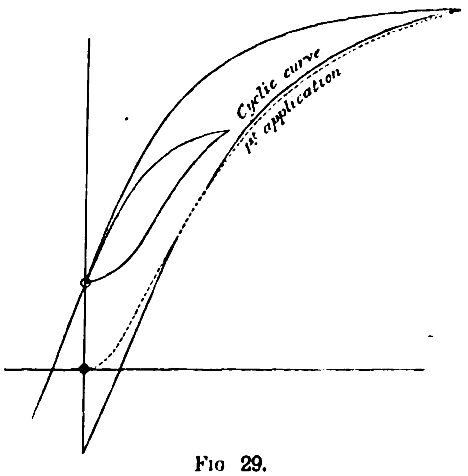

FIG. 29.

the constancy with which the movement repeats itself. In the last figure in the group of Fig. 28 the commutator was slowly turned by hand, and two minor loops were superposed on the main cycle.

Fig. 29 is another test made at the same time, and on the same metal as the tests of Figs. 26 and 27. It shows a small loop superposed on a main cycle, and also a curve (drawn in broken line), which is the magnetisation curve starting from zero, taken after the metal had been reduced to neutrality by the process commonly known as "demagnetising by reversals" —namely, by numerous reversals of a gradually diminishing magnetic force. Here is found a feature which was first

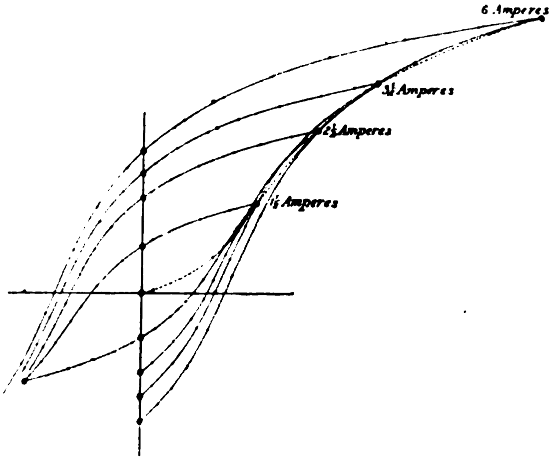

FIG. 30.—Cyclic Magnetisation of Soft Iron, shown by the Magnetic Curve Tracer.

remarked, we believe, by Dr. John Hopkinson, namely, that in magnetising from the neutral state the curve crosses the rising limb of the cyclic curve. The same feature has been looked for, and always found, in many other curve-tracer tests.

This crossing is in agreement with the fact already noticed, that the extremity of one cyclic curve projects beyond the rising limb of a higher cycle. For, after a piece has been put through the process of "demagnetising by reversals," the magnetising curve starting from zero, passes, as nearly as we can

* We are indebted to Mr. A. G. Dew Smith for these photographic recor

Digitized by Google

judge, through the projecting extremities of the cycles. Hence it lies outside of the upper part of the rising limb of any cyclic curve.

Fig. 30 gives a further illustration of these remarks. It shows a magnetic curve-tracer test of moderately hard steel, the dotted curve being obtained by magnetising from zero, after the process of demagnetising by reversals had been performed. This line will be seen to pass through the extreme points of the several cyclic curves, which thus overlap one another in the manner already described.

Fig. 31 is a study in superposed magnetisations in soft iron. Here the magnetic curve tracer was arranged with two independent magnetising coils upon the magnetic circuit under examination. One of these was used to apply a cyclic variation of magnetic force, while the other was used to apply a steady force of greater or less intensity, on which the cyclic force could be superposed. For brevity, we may distinguish the two circuits as P and Q. In the first place, after the iron had been demagnetised by reversals, the current in Q was applied, and was reversed repeatedly between equal positive and negative values, there being, at the time, no current in P. This gave the usual cyclic curve *a b* (Fig. 31), from which it will be seen that the magnetising force then applied by Q was comparatively small. Then (the piece having been again demagnetised) a current was set up in P, which brought the magnetism up to a value represented by the point *c* in the figure. This current in P being now kept constant,

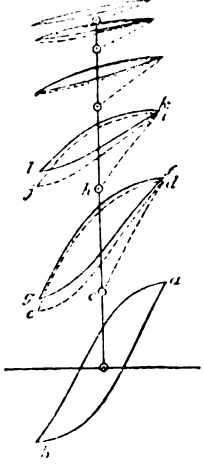

FIG. 31.

the current in Q was applied. This gave the line *c d*; then the current in Q was reversed, giving the dotted line *d e*, and re-reversed. Finally, after several reversals of the current in Q, the process of reversal gave the closed figure shown by the full line *f g f*. Next (the current in Q having been stopped), the steady current in P was increased to a value which brought the magnetism up to *h*. Then the application and reversal of Q's current gave the lines, *h i*, *i j*, *j k*, the cycle finally settling down after several reversals into the form shown by the full lines *k l k*. The same description applies to each of the loops which are seen higher in the diagram. The highest ones lie in what is often called the region of saturation. Throughout all these successive operations the current in Q, whose reversal formed the loops, had the same extreme value. The experiment shows how, as might be expected, the reversals of a given magnetising current produce less and less magnetic change as the total magnetism is increased. It also illustrates one of the minor consequences of magnetic hysteresis, namely, that a period force, applied in addition to a constant force, does not immediately produce cyclic effects; it is only after several repetitions of the reversal that the curves become closed. During the interval of "accommodation" (to use the term which has been applied in other instances where the same feature occurs in the phenomena of magnetisation) the mean value of the magnetism is rising, as a consequence, one may say, of the molecular shaking which is involved in the process of reversal.

(To be continued.)

COST OF ELECTRICAL ENERGY.*

BY R. E. CROMPTON, M.INST.C.E., VICE-PRESIDENT.

(Continued from page 727, Vol. XXXII.)†

FUEL AND WATER.—DIVS. 1 AND 2.—THE EFFECT OF THE EFFICIENCY OF STEAM ENGINES ON DYNAMOS OR ALTERNATORS.

Now that so many supply works have been running for several years, and that the works accounts have been annually published in the full detail demanded by the Board of Trade requirements, so that the actual cost of fuel, water, stores, labour and salaries, and actual output of energy delivered, are recorded, and are known to everyone who interests himself in these matters, it might be thought an easy matter to draw some useful conclusions from these published figures, so as to throw light on the comparative efficiency of the various systems and types of plant used in these supply works; but I regret to be obliged to confess that the drawing up of such comparative tables is not an easy matter. I have examined the published accounts of 23 important and representative electric supply works, in order to compare for this part of the Paper the cost of the fuel. From these I have prepared Table VI., which relates solely to fuel and water used. I must mention that in preparing this and the other Tables I at first relied on the published accounts for the information as to fuel, stores, labour, and salaries; but, as I found that several serious mistakes existed in the published analysis of such accounts, I in every case have taken the precaution of sending the figures to the engineer of each works, in order that he might satisfy himself of their correctness, and in most cases the engineers of these works have very kindly supplemented this figure by the other data required to bring this cost of fuel to a common basis for purposes of comparison.

The best method of comparing the comparative efficiency of the generating plant would be by comparing the weight of water evaporated per unit generated; but, as I have already pointed out when discussing the boiler question, this water measurement has been very rarely carried out, so that I am obliged to fall back upon the only certain measurement—that is, the weight of fuel used. I have written to all the engineers of the works named in these Tables, and have in some cases received full information, in others partial information, and in a few cases have been refused all supplementary information. In the cases where the information has been partially, or where it has been entirely withheld, I have been obliged myself to fill in the blanks by calculating them from the published costs and known calorific values of the fuel used. I have done this after having made careful inquiry in each case; and whenever there has been a doubt as to quantity price, or calorific value, I have endeavoured in each case rather to favour that particular works. At any rate, any errors that may exist in these calculated figures cannot be large enough to affect the result which I now bring before you.

In addition to the accounts of the 23 works examined, I have also examined the accounts of 10 foreign works; but I find their information is too incomplete and too difficult to bring to a basis of comparison with our English works, and I do not complicate my Table by adding them in.

Of the 23 English works examined, 10—viz., those at Bournemouth, Chelmsford, City of London, Eastbourne, House-to-House (London), Metropolitan, Newcastle and District, Newcastle-on-Tyne, Leeds, and Exeter—distribute the bulk of their output on the converted alternating system. Two works—viz., those at Chelsea and Oxford—distribute on the converted continuous system. Eleven works—viz., Birmingham, Bradford, Brighton, Charing Cross and Strand, Hove, Kensington, Knightsbridge, Liverpool, Preston, St. James and Pall Mall, and Westminster—distribute on the direct system.

* Paper read before the Institution of Electrical Engineers, April 26th.

† During the reading of the Paper the author made the following additions to the portions published in our last issue:—

After the words, "not a necessity," p. 726, left-hand column, line 6 from bottom, interpolate:—"Since this was written we have been almost continually making experiments, and we find it is undoubtedly true that by exercising very great care and watchfulness you can get as high an efficiency out of a Lancashire boiler as out of any other, but it must not be fired heavily. The great care means that you have to pay higher wages to the stokers, and any mistake on the part of the stokers affects the efficiency of the boiler, which might not be the case with a multitubular boiler. That is the real use of the economisers—they cover the errors and mistakes of the stokers."

On p. 727, at end of paragraph commencing "Referring to Table III. . . ." interpolate:—"Since writing this I have made repeated trials, with the result that on test trials that 5·2 evaporation can be brought up to 8lb., and can be maintained so long as the test apparatus is in position and you can advise the stokers what to do, but as soon as it is removed it falls down again. There should be some means of knowing what the composition of the escaping gases really is, for without some knowledge of the kind some very large errors are still made."

In Table VI. I have grouped these 23 works into these three systems of distribution, and have arranged them in each group in order, always heading the list by the works that uses the largest quantity of fuel. It is curious to remark that this system of grouping also divides them very fairly into the two great divisions of

1. Rope- or belt-driven plant.
2. Direct-driven plant.

In the first group I have averaged the fluel consumption in thermal units per watt-hour, omitting from the average the first-named works, as the conditions of working are somewhat abnormal; and, similarly, in the last group I have averaged the fuel consumption for the whole, with the sole exception of the first-named works—*i.e.*, Preston—the conditions in this case being also abnormal. These averages show that the consumption of fuel per unit sold in the first group is about 94 per cent. greater than in the direct group; but as this difference is made up very considerably by the difference in efficiency of distribution, I have calculated the actual fuel consumption at the terminals of the dynamo by the efficiency of distribution of the two systems, which I regret to say is in several cases an assumed figure, as in several cases it appears to be actually unknown to the works' engineers themselves.

The Table shows that, whereas the efficiency of distribution of the converted alternating systems is apparently somewhat under 66 per cent., with the direct systems (excluding the two-wire systems) it is about 86 per cent. The fuel used per unit generated in the converted alternating systems appears to be 43 per cent. higher than that used by the direct systems. In making these calculations I have carefully avoided considering those where a mixed system of distribution is used. The Table also shows that the fuel average of the works where the alternators or dynamos are rope-driven is about 46 per cent. higher than where the dynamos are direct-driven by high-speed engines; and I think that the information that the Table gives on this point is of the utmost importance, as it shows in a marked degree the economical advantages of high-speed direct-driven steam dynamos over slow-speed engines, driving dynamos, or alternators by ropes or belts.*

Eight years ago I stood almost alone when I recommended that the 1,200-H.P. load of the Vienna central station should be divided amongst eight steam dynamos coupled direct to high-speed engines, as at that time most engineers still believed that high economy in the use of steam could only be obtained by putting down long-stroke, slow-speed engines, such as are commonly used in cotton mills, and driving from these engines the dynamos by means of ropes or belts. This superstition was founded on the belief that steam could only be economically used in large engines of this type, which obtained their high piston speed by long strokes and few revolutions per minute; but it did not take long to show that the great variations of load in an electric supply works causes these huge engines to run for many hours at a very small fraction of their load, making them very uneconomical, so that the subdivision of their load between several smaller engines became necessary.

Mr. Willans, in his first and historic paper on steam-engine economy read before the Institution of Civil Engineers, was the first to strike a blow at the erroneous belief that economy could only be obtained from long-stroke slowly revolving engines, by showing that as the enemy to economy, particularly in the smaller engines, is cylinder condensation, the true way to reduce this is not by mere piston speed, as was the current belief, but by reducing the time during which the cylinder surfaces are exposed to the cooling action of the exhaust or of the condenser previous to each fresh steam admission—in other words, by using rapidly revolving short-stroke engines instead of slowly revolving long-stroke ones. Once this was understood, it followed that the high-speed engine making many revolutions, and therefore best suited for coupling direct to our dynamos, is also theoretically the most economical in use of steam. That this is also true in practice is shown by the long series of experiments carried out by Mr. Willans, and the figures that I am now putting before you. The advantages of direct driving are obviously not confined to the Willans, or, indeed, to any single-acting, type of engine; in fact, we have now a considerable choice of high-speed engines, all of which can be coupled direct to dynamos, and which use their steam economically. There is one advantage common to all direct-driven steam dynamos, *i.e.*, their high efficiency in $\frac{\text{E.H.P.}}{\text{I.H.P.}}$. This efficiency, which has been gradually creeping up from 80 per cent., which was the efficiency we obtained from the Vienna steam dynamos in 1886, to the very high figure of 88 per cent., which has recently been obtained by a Willans-Siemens combination, has been much commented upon, and has in some quarters met with actual disbelief; but all who know how accurately the tests bave been

* I should here state that the preparation of Table VI. has been the principal cause why this Paper has been delayed to such a late period of the session. The figures as printed in the proofs that you have in your hands have been altered several times, as additional information has been forwarded to me by the various engineers in charge. Even now I find that several mistakes and omissions exist. Some of them have been corrected on the the large Table on the wall, but those in your hand need correction as follows:—The averages of the first group include all the works mentioned with the exception of the Metropolitan and Exeter; the Metropolitan being for the year 1892, and the Exeter accounts being based on an estimated and not actually measured output. Again, the efficiency of distribution of the Chelsea Company, hence the calculation per unit generated ought to have been omitted. The figure given is that that would be obtained if the efficiency of distribution was the same as at Oxford. The Oxford figures came in at such a late period that I was unable to mention them in the body of the Paper. The results are very encouraging; in fact, I think they are too good to be true, especially when we come to consider the corresponding use of stores in Table VII. I have received a communication from Mr. Hunter, representing the Newcastle and District Company, in which he begs that I will make it clear that of the steam turbines used during the past year only one was condensing. He also demurs to the figures I have given of the B.T.U. per watt, as he says the calorific value of the coal used at Newcastle was only 7,250 instead of 11,300, the figures assumed by me. In explanation of my calculations, I may say that I used the figure 11,300 as furnished to me by Mr. Jackson, of the Newcastle-on-Tyne Company; but I believe that even this figure is too low, and that good Newcastle slack, such as any commercial man would purchase for steam raising purposes at Newcastle, has a value not less than 13,000. I use identically the same slack for my Chelmsford works, and pay for it a price that is not higher than is now paid by either of the Newcastle Companies, and I find on actual test that it has a calorific value of 14,000, so that I cannot accept Mr. Hunter's explanation that the high fuel consumption at Newcastle is due to the inferior quality of the coal used. I have also received a communication from the St. James and Pall Mall Company, altering the figures given in Table VI., which were the 1892 figures; the alteration is, however, entered on the Table on the wall. I must also say that I have not made any selection in the accounts entered in this Table. I have taken all the accounts that were ready at the time I prepared the Table, and those that are omitted were omitted solely at the request of the engineers in charge, on the ground that the only figures available, those of 1892, did not represent the present state of affairs,

Digitized by Google

carried out at Thames Ditton, and who have themselves made independent check tests, know also that such an efficiency can be obtained without difficulty—in fact, that efficiencies in excess of 86 per cent. can now be guaranteed at full loads, and 80 per cent. at half loads.

The case is far different with rope or belt-driven sets. In most cases it is difficult to obtain an efficiency of 78 per cent. at full load and 70 per cent. at half load when the engines are fitted with the ordinary unbalanced slide valve, or 80 per cent. at full load and 73 per cent. at half load when the engines have Corliss or balance valves. I must, however, note that Mr. Parker, in his Paper—read before the Institution of Civil Engineers—on the Liverpool Overhead Railway, gives us the satisfactory results obtained from slow-running horizontal engines driving dynamos by ropes; but, although I do not challenge Mr. Parker's ultimate figures, yet I think that without doubt he has made a mistake in his calculated efficiency—that is to say, $\frac{\text{E.H.P.}}{\text{I.H.P.}}$. I think that it would be difficult for me—or, in fact, for anyone who has paid much attention to the losses due to the friction of steam engines, and particularly of condensing engines, and to the losses occasioned by rope-driving—to accept Mr. Parker's figures. No one has made more careful experiments on the friction of such engines than Messrs. Sulzer, of Winterthur, and Messrs. Carels Frères, of Ghent, who make the same type of engines. I have been informed by the latter that an engine efficiency of 91 per cent. is only rarely obtained; generally the efficiency is somewhat lower. Mr. Parker states that the electrical efficiency of his dynamos is 97·7 per cent., which is an extremely high figure. If we take the commercial dynamo efficiency at 96 per cent., which is an outside figure when we consider the side strains on the bearings caused by the rope-driving, and if we suppose that the loss due to the rope-driving is only 2 per cent., which I believe is less than has ever been noticed, it is just possible, with a 91 per cent. engine, a 2 per cent. rope loss, and a 96 per cent. dynamo, to get 85·6 per cent. efficiency.

Although I do not believe that such an efficiency, and correspondingly small consumption of steam per electrical horse-power at full and half loads, can be obtained in practice by engines driving dynamos by ropes, yet it is so often attained by direct-driven sets that at least one maker can now guarantee figures very closely approaching the ideal figures I have given of 18½lb. of steam per unit at full load and 21½lb. at half load. Yet in the cases of direct driving such high efficiency is easily accounted for. In the first place, the engines are fitted with piston valves, which are the most perfect form of balanced valves; hence the internal friction of the Willans or Chandler engines, running as they do with all their parts thoroughly bathed in oil, must be probably lower than that of any other type of engine. Moreover, with direct driving there is no side strain whatever on the dynamo bearings; and even the downward pressure on these bearings can be partially eased by so placing the armature core in relation to the bore of the magnets that a certain amount of lift is given to the core at the time that the magnets are excited. Under such conditions it will be seen that the engine and dynamo mechanical friction can be reduced to a minimum—in fact, to a point very far below what is possible when any form of rope or belt driving is used. The figures that I now give show that the best results yet obtained have been with Willans engines driving direct-current dynamos; and I believe this is mainly due to the great reduction of friction which I have just mentioned, and which tells heavily in favour of this class of steam dynamo when it is only partially loaded. Hence we find that, whereas the combined efficiency of a Willans combination is as high as 80 per cent. at outputs as low as two-thirds full load, the combined efficiency at two-thirds load of a slide-valve engine driving a dynamo by belts or ropes rarely exceeds 70 per cent.; and unfortunately, however much we may desire to keep the load-factor of the engine about 66 per cent., or two-thirds, yet under existing circumstances it is a matter of difficulty to do so even in works where accumulators are used, and in works where there are no accumulators with all converted systems the average engine load-factor appears to be far below this.

As you no doubt expect me to express an opinion as to the cause of the wide differences in economies of fuel shown in these comparative tables, I must point out that even, if we exclude the difference in distribution efficiency by making the allowances that I have done, there still remains three sources of loss—one already dealt with under the heading of the boilers, and the second due to the engines, dynamos, or alternators, and the third to losses which have been called by Kennedy "obscure works losses." Now I think the main cause of the difference in engine and dynamo losses lies in the fact that in the works under consideration the engines have been driven at widely differing load-factors; and, as whenever the engine load-factor is low the use of steam is correspondingly high, I think that this question of engine load-factor is of supreme importance. As I have shown above, a low engine load-factor tells more against belt or rope-driving sets than against direct-driving ones; but in neither case has the subject received the attention that it deserves. Every facility should be given for the men in charge of the steam dynamos to ascertain for themselves at any time at what load-factor they are driving their plant, and if this were done more frequently I am sure that great improvements would result. One reason why at present the men in the supply stations know so little about this question is, that in most cases it is only looked into as a sort of holy mystery by the engineering staff, and at long intervals of time; whereas I feel strongly a book ought to be kept in every works, and the men in charge should always enter up the load-factor of each engine during the hours the stop valve is open; and in order that this may be done with a minimum of labour, I have devised and used in our Chelmsford works a system which I will here describe for the benefit of those who care to adopt it.

The diagram* before you has its base line marked off in percentages of the load of the engine; and the same line is, in addition, marked with the steam-chest pressures, corresponding to these different percentages of load. This steam-chest pressure can be noted by a carefully calibrated gauge fixed on the steam-chest of the engine, the calibration being carried out as each set of indicator diagrams and electric load readings are taken; the result being that the man in charge of the engine can see at a glance from these steam gauges what ought to be the indicated and corresponding electrical horse-power that his engine is giving, and from the same diagram he is able to calculate the consumption of pounds of steam per hour.

Opposite to each gauge pressure is entered the theoretical consumption of steam per horse-power per hour at the standard speed, ascertained from Mr. Willans's table. Thus, if the man in charge enters up these steam pressures of all the running engines every quarter of an hour, it is easy to prepare an accurate report on the engine load-factor of the day, and thus compare the calculated with the actual steam used during the run; so that men who habitually underwork their engines can be thus noted and reprimanded.

Of course I know from experience how much more difficult it is to work engines driving alternators at a high load-factor than is the case with continuous-current steam dynamos. This is partly caused by the comparative difficulty and complication involved in parallelising alternators, compared with the ease of throwing continuous dynamos in and out of parallel on a storage system. In the latter case the enginemen have only one order to observe, viz., to keep their engines as fully loaded as possible on a rising load, not to start an additional set until the sets previously running are considerably overloaded, and on a falling load to shut down the sets at the earliest possible moment, even if it leaves the remaining sets somewhat overloaded for some time. Unless such orders are given and carried out to the letter, so that engine load-factors exceeding 70 per cent. on the average are obtained, it is useless to expect to reduce the consumption of steam below 50lb. per unit generated.

The other causes of waste of steam in electric supply works are those which Prof. Kennedy, in his lecture at the Royal Institution, speaks of as "losses about which we engineers feel very sore, and which sometimes try our temper and our patience greatly, and are not recognised as having any kind of respectable existence." These are those connected with leaks from boiler fittings and steam pipes, with condensation losses in the steam pipes, and due to the wasteful use of steam by all present known means of boiler feed.

These losses have been ignored by engineers, and have never received the attention they deserve; but, as they continue throughout the 24 hours, they amount to a very considerable percentage of the steam evaporated by the boilers, and of course tell most during the summer months, or in fact, in any works where the load-factor is low. Engineers who have been most successful in dealing with these difficulties, and have minimised these losses to the greatest extent, are those who previous to entering electrical works have received a practical engine-room training, either as sea-going engineers, or in engine-rooms of a similar class where fuel economy has been persistently studied. I believe the best remedy for the pipe condensation losses will lie in the direction of superheating the steam after it leaves the boilers. If we could superheat the steam so as not only to have no pipe condensation at all, but to deliver the steam to the engine cylinders at a temperature 8 or 10 per cent. above the corresponding temperature for saturated steam, I believe that we should at once save nearly 10 per cent. of the steam that we now have to evaporate in our boilers. It is very easy to talk of superheating steam. In the days of low-pressure steam at 15lb. pressure such superheating was a reasonably easy matter; but the case is widely different when the high-pressure steam leaves the boiler at a temperature of 375deg., as is now the case. Any further superheating is very much in the nature of passing this steam through pipes at a temperature which nearly amounts to red heat, so that it is little wonder that not

* We regret that we have not been able to obtain copies of the diagrams illustrating the Papers. [Ed. E.]

Digitized by Google

many engineers have cared about tackling such a difficult and risky problem; but it is quite certain that this problem will be tackled, and I have recently heard that it has been satisfactorily dealt with by Messrs. McPhail and Simpson, the superheater consisting of a large number of bent tubes made of thick lap-welded iron, each tube being only about 1in. diameter. The bent portions of these tubes are so placed that they are exposed to the hot gases when they first pass through the flues of the boiler, such as the space at the end of a Lancashire or of an "Economic" boiler; in the case of the Babcock boiler it would be more difficult to find a place for them. It is evident that whoever attempts to deal with this problem of working out a satisfactory superheater will have a great many difficulties to deal with. The superheater must, as I have said, be placed so as to be exposed to the high-temperature gases, and yet it must be accessible for ready replacing of the tubes and for repairs. Moreover, it must be easily put in and out of circuit, so that a failure of one of the tubes should not in any way cripple the steam supply of the works. These requirements are in a sense contradictory, but I have no doubt, now so many minds are directed to this problem, it will be successfully dealt with.

Another point which is receiving the attention of all of us is the extended application of condensing plant.

In situations where condensing water is available this problem presents no difficulty, but in a large number of cases condensing water is not available; and of late years—in fact, dating from the time of my 1891 Paper—a number of proposals have been made to introduce what are called evaporative or surface condensers, which may be described as consisting of a very extended surface of tubes through which the steam passes, the tubes being cooled externally partly by an air-fan blast, and partly by a limited supply of water trickling on to the outside of them. Of course, so long as the amount of water used is equal to the feed water used, there would be no advantage in using such a condenser, other than that the steam consumption may possibly be economised, especially at times of light load, so that the steam that is required to pass through the condenser would be proportionately reduced; but Mr. Ledward and several other gentlemen who have paid attention to this subject are confident that they will be able to eventually reduce the cooling water required to two-thirds of that of the ordinary feed water; and if this is the case, it will result in a very great advantage, not only in removing the nuisance—which some people insist is a real nuisance—of the steam issuing from the chimneys of the various supply works, but the difficulties with the boilers will be also greatly diminished. But it must be recollected that this use of condensing water entails the working out of several very difficult problems connected with the thorough filtering out of the oil contained in the exhaust steam before it is allowed to re-enter the boilers. The united opinion of nearly all boiler engineers and inspectors is to the effect that if the water contains the smallest percentage of carbonate of lime the entry of even minute quantities of oil into the boiler is likely to have disastrous effects. The oils forms with the carbonate of lime a covering to the flues and tubes of a highly non-conducting nature, which allows the iron or steel plates or tubes to be greatly overheated, and great damage is thus done; so that most boiler insurance companies absolutely forbid the returning of condensed water to the boiler unless it has previously passed through a purifying apparatus which absolutely frees it from the oil.

I have briefly mentioned how very considerably the wasteful nature of the steam pumps that are at present available for boiler feed pumps affects the total economy of the works. For some time past at Chelmsford I have attempted to deal with this difficulty by supplying my boilers with feed pumps electrically driven; and although these electrically driven feed pumps are by no means as efficient as I hope to make them in the future, yet in their present state their use shows a marked economy over the Worthington or other direct-acting pumps that were previously employed. The electrically driven pumps use the energy from the main switchboard, which is generated in an economical manner; whereas the direct-driven pumps are driven not so much by steam as by water condensed in their steam pipes. I have over and over again called the attention of pump makers to the great want there is of a more economical steam pump than is at present in the market; but there appears to be a difficulty in dealing with the question, I believe chiefly owing to the intermittent way in which these feed pumps are worked, so that between periods of working their supply steam pipes get comparatively cooled.

I have spoken of the difficulty I have met with in obtaining trustworthy figures as regards water consumption. This is mainly due to the fact that a thoroughly trustworthy water meter is not an easy article to meet with. In order that such a water meter may accurately record the water fed into the boiler, it ought to be placed between the feed water heater and the boiler, so that any leakages that may occur at the pumps themselves, or in the lines of pipes, or in the feed water heater itself, may not affect the question of boiler evaporation. This necessarily means that such a water meter must pass hot water. For several years past I have been using Schönheyder's meter in this position, with fairly satisfactory results, but in its present state it leaves much to be desired. The pins wear to such an extent that in our Chelmsford case we find it necessary to take the meter out and replace the pins and recalibrate it once every three or four months. The calibration of such a meter is not a difficult matter if the feed water in any part of its course passes through a rectangular tank, the cubic contents of which can be readily measured, and the water contained marked for each inch of height.

(To be concluded.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, May 4th.

LONDON CHAMBER OF COMMERCE.

2:30 p.m. Meeting of the Electrical Trade Section at Botolph House, Eastcheap, to consider the Locomotive Acts in relation to the Traction industry.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 28, Victoria-street. Paper to be read: "A Description of the Electrical Type-Printing Instruments as used by the Exchange Telegraph Company," by F. Digby Latimer.

SATURDAY, May 5th.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture: "Colour Vision," by Capt. Abney, F.R.S.

MONDAY, May 7th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture: "Typewriting Machines," by H. C. Jenkins.

TUESDAY, May 8th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Rubies," by Prof. J. W. Judd, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. The following Paper will be further discussed: "The Manufacture of Briquette Fuel," by W. Colquhoun, Assoc.M.Inst.C.E. After which the following Papers will be read: (1) "Recent Types of Ferry Steamers," by Andrew Brown, M.I.C.E. (2) "The Birkenhead Ferry Boats 'Wirral' and 'Mersey,'" by William Carson, M.Inst.C.E.

WEDNESDAY, May 9th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read: "Telegraph and Trade Routes in Persia," by Col. Wells.

THURSDAY, May 10th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Solid and Liquid States of Matter," by Prof. Dewar, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. Continuation of discussion on "The Cost of Electrical Energy," by R. E. Crompton, M.Inst.C.E.

FRIDAY, May 11th.

PHYSICAL SOCIETY.

5 p.m. The following Papers will be read:—(1) "Electromagnetic Induction in Plane Cylindrical and Spherical Current Sheets," by G. H. Bryan, M.A. (2) "Dielectrics," by R. Appleyard.

SATURDAY, May 12th.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture: "Colour Vision," by Capt. Abney, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Electric Light and Power Stations in Germany.—In Germany use has already been made of electric light stations for the purpose of supplying power to electric tramways. At Hamburg the consumption of the tramway already amounts to one-quarter of the total output of the station, and at Aix-la-Chapelle it has been decided to run the proposed tramways by means of current supplied from the electric lighting station.

SPECIAL NOTICE.

Last week's number of "THE ELECTRICIAN" completed Vol. XXXII. With this week's issue is published (Gratis) the Index to that Volume.

NOW READY.

Volume XXXII. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.

Cases for binding Volume XXXII., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

PATENT AGENTS.

This is an age of hysterics. In literature, in art, in politics, in business, and even in science, screaming is the fashion. The vulgar form of attracting attention is mere screaming on the part of the author, artist, demagogue, or prospectus writer or company wrecker; the more approved mode is the production of something calculated to make others scream. Pure science is tolerably free from this evil, but on its fringe we have anti-vivisectors, anti-vaccinators and anti-4πists who amply make up for any shortcomings elsewhere. Science and business may be said to meet at the Patent Office, and it seems impossible for some people to approach the patent question in a temperate fashion. As in other social problems, when "rights" are under discussion, common sense is too often found to be at variance with political ethics. Inventors, it is claimed, have a positive right to the fruits of their creative ingenuity, and when the Government, in exchange for a very valuable consideration, exacts anything more than a mere nominal registration fee, there are cries about the "taxation of invention." There is much to be said against the general principle of patents; but experience has shown that, on the whole, some such artificial bargain as that which the State now offers to inventors is useful, in so far that it encourages them to develop their schemes, of which a small fraction may eventually prove to be useful to the community. The popularising of the patent system by the Acts of 1883 and 1888, by which fees were largely reduced, and under which applications could be made to the Patent Office through any post-office in the kingdom, had the effect of largely increasing the applications; but the abandonments rose in even higher proportion, and at once exceeded the patents granted in former years. Re-

Digitized by Google

formers were not satisfied, and the highly-coloured complaints about the taxation of invention and the hardships of patentees were soon renewed. In 1892 large concessions were made by the further reduction and simplification of the maintenance fees.

Again the cry is raised that "the inventor is being robbed." This time it is not the State directly, but the patent agents who are being howled at. The cause is to be found in two Bills now before Parliament. These two Bills, professing to aim at the proper registration of duly qualified patent agents, differ widely; but the whole difference, though one of grave importance, is to be found in the introduction of one little word of three letters. It is hardly credible that a Bill backed by such names as R. C. H. Gibbs, Sir Reginald Hanson, W. F. D. Smith, H. Kimber, Dr. Farquharson, A. Birrell, and last, but by no means least, by Sir Albert Rollit, should propose that no unregistered person shall be entitled to *act* as a patent agent, under a penalty of a fine not exceeding twenty pounds for a first offence, or to imprisonment for a term not exceeding six months for a subsequent offence. The Bill is promoted by a new body calling itself the Society of Patent Agents, and, besides inviting incorporation and registration of its present members, it seeks powers of government and of future addition to its numbers by sundry bye-laws. These bye-laws contemplate pure autonomy, and their only redeeming feature is, they are not to come into effect until they have been submitted to and allowed by the Board of Trade. But the Bill, in proposing to punish any unregistered person who assists another to draw up a specification, is so absurd that it really deserves no further attention.

The other Bill is introduced under the auspices of the Chartered Institute of Patent Agents, a body which has been not only officially recognised, but has been entrusted since 1889 with important duties, by the Board of Trade. It clearly states in its memorandum that its object "is not to create a monopoly, but to regulate the profession of patent agents in a manner similar to that in which other professions, such as those of solicitors, veterinary surgeons, and dentists are regulated." It "protects the public from deception by the unauthorised assumption of the title of patent agent." It forbids any person other than a registered patent agent using the title of patent agent under a penalty not exceeding twenty pounds, and we are glad to observe that it forbids also the use "on his place of business or elsewhere, the words patent office," a practice which ought long ago to have been stopped in all cases. The promoters, naturally jealous of their royal charter, ask for protection of the title "chartered." They have already adopted a system of tests of professional qualification, and their Bill schedules certain examinations, and the whole object of the Institute is to protect the public and prevent the "fleecing of inventors."

These Bills have raised a silly and indiscriminating outcry against patent agents as a class. There are, of course, many black sheep—utterly unqualified, as well as dishonest, men—among them. The temptations to which weak-minded patent agents are liable were well set out in *Engineering* last week, and it is difficult to imagine what possible inducement there can be, unless in a small town, for an inventor to go to one of these men. There are, we believe, no less than 46 Fellows of the Chartered Institute in London, and 26 in the provinces. London is unduly favoured in this as in other respects; and in the matter of patenting, the non-Londoner is at a considerable disadvantage, for he is often unable to consult a good patent agent or to examine published specifications without making a considerable journey. A large number of patentees employ no agents, and no doubt many engineers who have seen three or four specifications put through by a good agent are capable of turning out fairly good home-made ones. If they apply for two or three a year and drop three out of four at the end of the fourth year they certainly save a few pounds and perhaps gain some experience. But anyone with an invention which really promises to be a valuable matter will do well to discuss it with a good patent agent. The employment of a patent agent may be compared to the employment of a doctor or of a solicitor. For mild ailments, or for simple agreements or wills, an intelligent amateur treatment may be sufficient; intelligence, of course, implying an acquaintance with elementary principles. The amount of care and attention bestowed, to say nothing of valuable advice in drafting, as well as practical suggestions given as to the carrying out of the invention, is probably cheaper for the money than any professional services of the solicitor or of consulting engineer. It is rather flattering to an inventor to think that the agent has practically passed his draft specification with hardly an alteration. This alone is worth half the fee, and the feeling of security that two such wise heads have agreed on the settlement of the momentous document is worth the other half.

It is a great pity that the excitement, the circulars, the petitions, and general fuss about the robbing of inventors that is now being made should be directed against both of these Bills. We have little fear of the result. After encouraging and facilitating in so many ways the application for patents by the public, and after thus throwing open the Patent Office to them, it is hardly conceivable that the Board of Trade should forbid inventors to apply except through a patent agent. This it is not asked to do, although it is, of course, quite impracticable to prevent advice either in connection with the invention itself, or with the drafting of a specification being given either for fee or no fee, by a consulting engineer or by a friend of the inventor. We so highly esteem, on the other hand, the services of experienced patent agents, that we welcome any measure which will strengthen their position, and, if possible, sweep away the disreputable speculators and sharks who so disgrace this honourable profession, and are the real causes of the agitation concerning the "robbing of inventors." This can always be prevented if only inventors will take the trouble to enquire into the professional status and qualifications of any patent agent they may think of employing.

PROF. A. B. W. KENNEDY'S PRESIDENTIAL ADDRESS TO THE INSTITUTION OF MECHANICAL ENGINEERS.

(Continued from page 718, Vol. XXXII.)

I pass now to the last and largest section of my subject, the question of public electric lighting from the point of view of the mechanical engineer. From the side of the public, that is, of the users of electric light, the essential points are simple, viz., that the light should not visibly flicker, that it should not be below the declared pressure nor very much above it, that it should be available at all hours, and of course most of all that it should never go out! But any notions one might have that in consequence of the simplicity of this final result the means of attaining it would also be simple, are very speedily dispelled by a consideration of the facts. It is, alas! not sufficient to provide a shed, a boiler, a decently-governed engine and a dynamo or alternator, and many and sad have been the disappointments in consequence. The fact is, that although the final result to be attained is always the same, and is always extremely simple and straightforward, the conditions under which that result has to be obtained are always varying, and are not only extremely complex in any one place, but are also different altogether in each different place. To members of this Institution, however, I need not point out that

Digitized by Google

this is not any cause for grumbling—the more difficult and complicated the problem the more chance there is for the engineer in working out its solution.

I will consider first those variations which are entirely beyond the control of the engineer, *i.e.*, the variations of load, and afterwards those which are within his power, *i.e.*, variations in the working of the station. To those of you who have practically to do with these matters the variations I have to speak of are absurdly familiar; but to others—probably the majority—they are still sufficiently unfamiliar to be of some little interest. I have, therefore, prepared diagrams which may illustrate them.

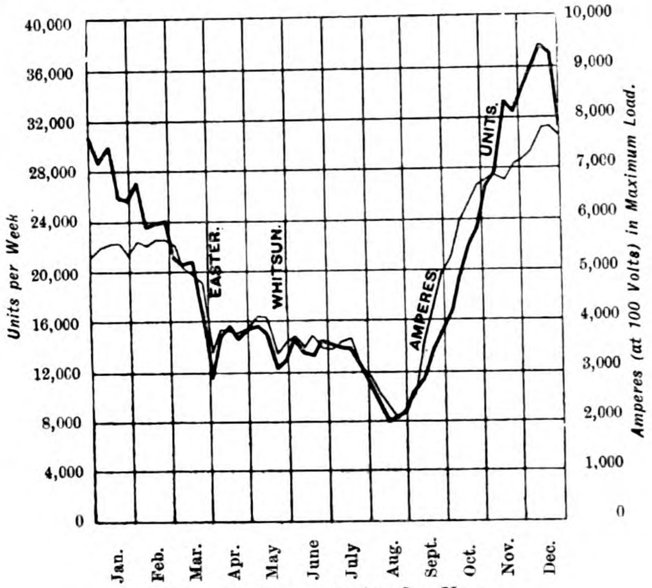

Fig. 1.—Output during One Year.

Diagram 1* shows the variations of output of a lighting station during a whole year. Each vertical division stands for one week. Irregularities are due to particularly foggy weeks or to weeks in which public holidays occur, such as Easter and Whitsuntide. For the rest the curve follows pretty obviously the changes in daylight, except that the minimum occurs, not in the very middle of the summer, but during August, in consequence of the large number of private houses which are shut up at that time while the days are still too long to require the use of any artificial light in shops which close at 7 o'clock.

Diagram 2 shows the variations within a week, each vertical division standing for one day. Here, of course, the chief variation is that which occurs on Saturday and Sunday.

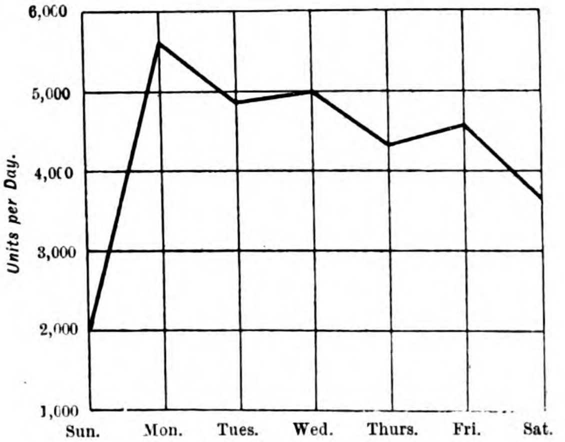

Fig. 2.—Output during One Week.

Diagram 3 shows the variations occurring within one day, the vertical divisions each standing for one hour. In this diagram three days are actually shown, one in December, one in August, and one in June, and it will be noticed that the three are very different. In winter there is practically always a double maximum, one occurring about breakfast time or in the forenoon, after which the load falls off in the middle of the day and reaches its full maximum towards evening. In the summer time the morning load disappears altogether, and there is only one maximum, which occurs much later than it does in winter. In fact I have noticed that in London at any rate the average time up to which people use light is fully an hour later in the summer than it is in the winter, a somewhat interesting fact in sociology. In August the "peak" of the diagram becomes a minimum, the private houses using no light because they are closed, the shops because the days are still too long.

The thick line on Diagram 1 shows in rather an interesting fashion that the maximum load and the minimum output by no means vary together. The maximum load is much more constant than the maximum output, and does not vary nearly so fast or so much.

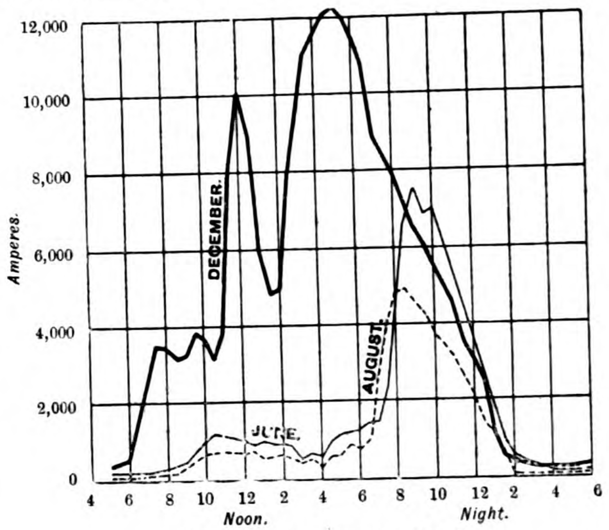

Fig. 3.—Load Curves. London.

The quantity which chiefly varies is the time during which that load lasts, and this time is, of course, dependent on the hours of sunlight, or more particularly on the interval between sunset and closing or bed-time.

Besides the variations shown in these diagrams it is right that I should mention one or two others. A very important class of variations are those which may be said to be due to latitude. In a place as far north as Aberdeen, for instance, there is practically no night for two months in the year, and for a much longer time than this no lighting whatever is used in shops, and hardly any in private houses. On the other hand, the hours of lighting in the winter are proportionately longer than in the south. The effect upon the annual output diagram would be not to alter its area considerably, but to thicken it up in the winter and reduce it very much in the summer. As an illustration of northern loads I have shown in Diagram 4 load curves for a winter and a summer day, taken at a little station which was running in Glasgow supplying offices some two years ago.

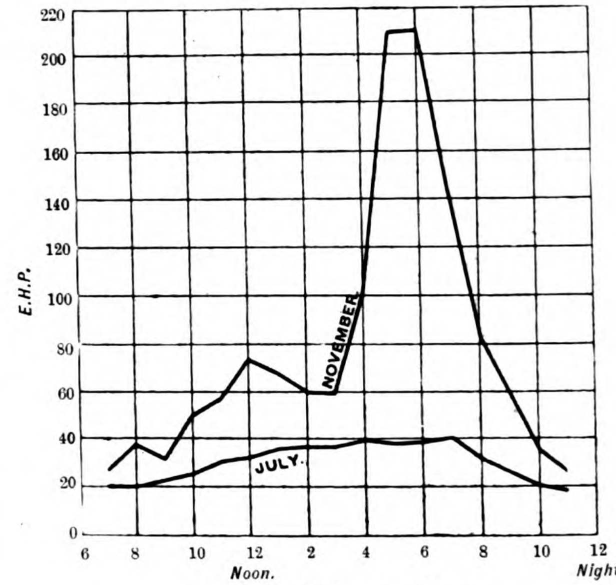

Fig. 4.—Load Curves. Glasgow.

One set of variations which puzzles and troubles the engineer very much is the varying amount of light thought necessary by

* This diagram corresponds to the output at the Davies-street Station of the Westminster Electric Supply Corporation during 1893. The great excess in the last quarter over the first quarter is to a considerable extent due to the larger number of lamps which were on circuit towards the end than at the beginning of the year. The great drop in the last week of all is due to the fact that that week included Christmas Day and Boxing Day as well as a Saturday and Sunday.

Digitized by Google

people in different parts of the country. No doubt this depends to a considerable extent upon the nature of the premises in which the light is used, but even this is hardly sufficient to explain the whole of it. In a purely residential district in London, for instance, the average energy used per annum is only about 12 units per lamp wired. In a mixed district like that of the Westminster Company it is about 16 units per lamp wired. In a very rich district containing many clubs, like that of the St. James' Company, one is not surprised to find that it amounts to 22 units per lamp wired. But one is on the whole surprised to find that in Newcastle it should be as much as 25 units, and in Leeds 27. It is no doubt with less surprise that one notices that the consumption of 38 units per lamp per annum which existed in Exeter when current was paid for by contract and not by meter, was exactly halved as soon as consumers were made to pay for the amount which they really used.

There is one set of variations which, unlike all those which have been mentioned above, is to a certain extent under the control of the engineer. I mean the variations on the two sides of a circuit which is arranged upon a three-wire system. Here, of course, the engineer, in the first instance, endeavours to connect about the same number of lamps wired on each side of his system, and to see that the balance is approximately right, not only over the whole system but over each small section of it. In spite of all the care that may be used in this matter, however, I have found that a three-wire system may be very often greatly out of balance for a few minutes at a time owing to causes entirely beyond the engineer's control. Rapid changes in this respect occur chiefly within the 15 or 20 minutes during which load is coming on most rapidly in the afternoon. In a station when the load was increasing from 2,000 up to 8,000 amperes, I have frequently seen that in the course of 10 minutes first the positive and then the negative side would have 400 or 500 amperes more than the other. By the use of a balancing machine which can be transferred by a single switch from one side to the other the case, of course, can be met as it arises, but it is sometimes a little surprising that the changes should be so large and so rapid.

I have endeavoured to indicate to you some of the great number of variations in conditions, in spite of which the engineer has to obtain a uniform result. All these variations, even the last, are practically altogether beyond his control. Some of them occur with considerable regularity and can be foreseen, others are most irregular and come without any warning whatever. But all of them affect very greatly both the method and the cost of production. The method first, because the efficiency and regularity of supply must be considered before the matter of economy. Any method of supply which was inevitably liable to breakdowns and interruptions would be wholly condemned on that ground alone, even if it happened to be of the very highest economy. But given any one of the many methods of supply which are equally good as to result to the consumer, then that method must mainly be judged by its economy under the particular conditions in which it has to work. It will of course be borne in mind that the cost of power production in this case is not a mere 3 or 4 per cent. as in the case of a factory. It is 50 or 60 or 70 per cent. of the whole expenses, the balance being expenses of management and distribution, along with interest, depreciation and other charges connected with capital.

As to the effect, then, of the uncontrollable variations on system or economy, the first thing which I have to point out is that their madness is not entirely without method. There are some points which are as certain as it is that all Members of Parliament will not be on one side, in spite of the fact that such a thing is in imagination conceivable! Two of these are of special importance. First of all, there will never be more than certain proportions of all the lamps which are wired alight at once, either at times of maximum or of minimum load. The maximum maximum on the circuit of the Westminster Company is about 35 per cent., on that of the St. James Company I believe over 60 per cent., of the House-to-House Company about 35 per cent. In Glasgow, where at present the light is solely in the region of offices and shops, the proportion is as high as 56 per cent. You will see that these proportions depend largely upon the nature of the places where the light is used. This proportion, which, of course, can be only an estimate in any particular place until the experiment is made, fixes for the engineer the maximum number of lamps wired for which a given horse-power will supply current.

The maximum minimum is an almost equally important quantity, and in most places the engineer has to do with two such maxima, one for the day hours and another for the night. In a purely residential district the night load will always be very small and the day load will be practically nil. In the City of London the day load, in consequence of the number of dark places to be lit, is considerable, the night load extremely small. In a mixed district like that of the Westminster Company, the day loads, in the middle of summer, is not greatly more than the night load. It is to be noted, however, that the night load is practically the same all the year round, while the day load, even apart from fogs or exceptional weather, necessarily varies very much. The maximum maximum, also, as we have seen, varies much at different times during the year, although it never exceeds a certain amount. It is also worth noticing that in general the night load on a central station will increase but slowly with the growth of the station. The first consumers who take the light are most often those who are most in need of it, who require it for dark corridors and long hours. Later on thousands of lamps may come on to a circuit in shops, offices, and in ordinary private houses, without a single one of them being used after midnight. In an average district the day load increases faster than the night load, because out of any large number of shops and offices some are sure to have dark places requiring current in the daytime. But neither night nor day loads increase nearly as fast as the maximum evening load, which—a certain normal condition having once been reached—will increase exactly in proportion to the lamps wired. In an alternating current station where very numerous isolated transformers are used, the night load increases nearly proportionately to the day load because of the increase of magnetising current.

The determination of the sizes of units to be used in any station depends essentially on the probable values, absolute and proportionate, of the loads I have mentioned. It is now a commonplace, although a few years since no one seems to have thought of it, that the machinery in a station should be so subdivided that under all sets of conditions which remain steady for a few hours at a time it should be possible to have such machinery as is running, running more or less nearly fully loaded; only in this way can much economy be hoped for. It must not be taken, however, that this is a mere question of arithmetic, which can readily be settled offhand. In every case—it is to be hoped—the output of a station will be much greater ten years hence than it is to-day. The engineer has not uncommonly to consider somewhat difficult *pros* and *cons* when he is called upon to provide machinery which shall be of such a type that it can allow dividends to be earned during the years of growth and yet remain still suitable in the time of maturity.

It is further to be remembered that this question of the choice of size of unit is also quite modified in the cases where condensing plant is used instead of non-condensing. The reason for this I will not discuss here; I had a good deal to say about them in a recent discussion at the Institution of Civil Engineers. A good condensing engine uses nearly the same steam per indicated horse-power-hour at any load above half output. The increased consumption per estimated horse-power-hour is therefore proportionately much less than in the case of non-condensing engines, and the economical importance of fully loading the machines is correspondingly minimised in stations where condensing plant is employed.

The question of size of unit leads naturally to that of the necessary magnitude of reserve in any case. I think this is a simple matter, but no doubt it is sometimes wrongly treated. To make the reserve a fixed proportion to the total plant for instance, is a method which can only possibly come right by a fluke. I will not argue for the necessity of a reserve—that appears to me to be beyond any argument. The reserve is required for two purposes—to provide against breakdown of plant and to provide against accidental increase of load on special occasions. It is in the primary conditions of the case that the light absolutely must never go out, even if a machine wholly breaks down at the time of full load. From this it follows as a mere matter of arithmetic that the minimum of reserve must be a unit equal in size to the largest unit in the station, so as to be capable of taking its place if it breaks down. I should have thought that it went without saying that a machine of 100 H.P. could not be a reserve in a station where other machines were of 200 H.P., had it not been that I have seen it often so said. If an engineer considers that the winter, when the full load is liable to come on at any moment, is a suitable time for overhauling his plant, it is obvious that the reserve must be at least double the minimum which I have mentioned. Indeed most engineers would prefer to have two strings to their bow, and not to know that the breakdown of one machine would absolutely use up the reserve they wanted to keep in case of specially heavy load coming on, as long as it (the breakdown) lasted. This, however, is a question of degree, of caution, and some would say also of nervousness.

(*To be continued.*)

Electromagnetic Synchronism.—An elaborate and exhaustive Paper on "La Synchronisation Electromagnetique" is published in the *Bulletin de la Société Internationale des Electriciens* for April. It is from the pen of M. Cornu, and deals with the subject with that completness and careful analysis which is characteristic of M. Cornu's work. Commencing with the discussion of geometrical and mechanical analogues, such as the pendulum, the theory of electromagnetic synchronism is evolved, and the principal theorems in connection therewith are discussed.

DESTRUCTIVE EFFECT OF ELECTRICAL CURRENTS ON SUBTERRANEAN METAL PIPES.*

BY ISAIAH H. FARNHAM.

For the past year or more there have been read before water, gas, and electrical engineering societies all over this country, Papers on the subject of electrolytic corrosion of water pipes, gas pipes, and lead cables. In fact, a meeting of such societies is incomplete to-day without some discussion on this subject. It was, therefore, with hesitation and misgivings that I considered the written invitation from the officers of the Institute to prepare a Paper on the "Electrolytic Effect of Currents on Subterranean Gas and Water Pipes."

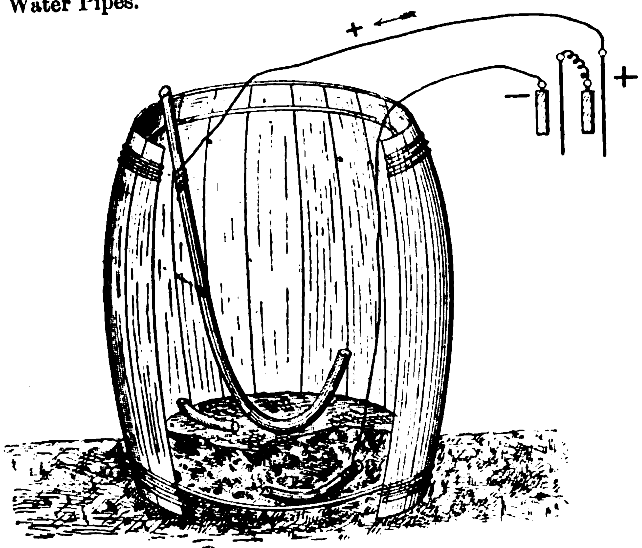

Fig. 1.

Early in the summer of 1891 some lead-covered telephone cable removed from wooden ducts in Boston showed some very marked yet local spots of corrosion. The cause of the corrosion was generally attributed to acetic acid contained in the wooden conduit, which had, years before, caused corrosion on a few cables in certain sections of the city. In the case just mentioned the corrosion was so severe, and located in spots only, that it led me to attribute the cause to electrolytic action from the railway currents, and a letter was written to my company to that effect. A few months later the repaired and raised from the ground, and found 1·5 to 2 volts difference of potential, the cable being positive to the earth. A barrel of earth (*see* Fig. 1) was procured from an excavation in the street, a metal plate placed beneath the earth in the barrel, and two short pieces of lead cable placed side by side on top of the earth. The plate in the bottom of the barrel was then connected to the negative side of a storage battery giving 4 volts potential, and one piece of the cable lying on the earth, was connected with the positive pole of the storage battery. The second piece of cable in the barrel was left without electrical connections. The earth was then saturated with water, and the circuit was closed, allowing the current to pass from battery to cable, to earth, to plate, and to battery, for seven consecutive days. The pieces of cable were

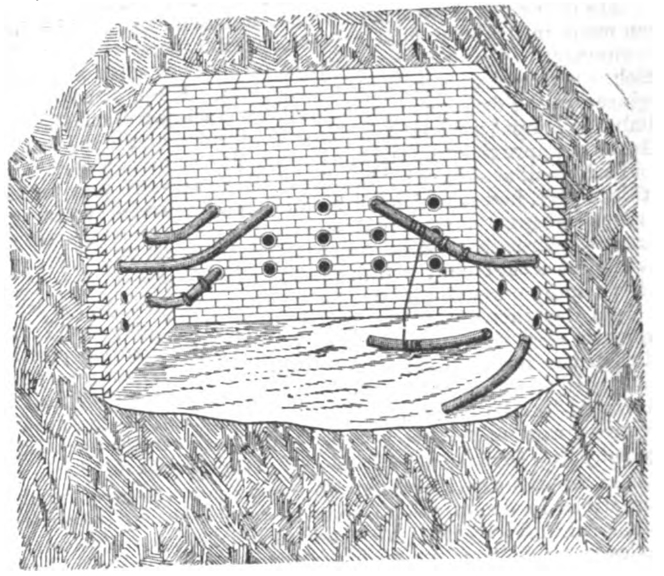

Fig. 2.

then removed and the piece which had been connected with the battery was badly pitted, closely resembling the cable which had been destroyed, while the second piece of cable showed no corrosion whatever, proving conclusively that a current such as was found in the manhole, was sufficient to cause the damage that had been found, and that the corrosion was not, in the case of the experiment at least, due to any acid or salts in the earth. In addition to the experiment just mentioned, we placed in the bottom of manhole chamber No. 76, two short pieces of cable, one of which

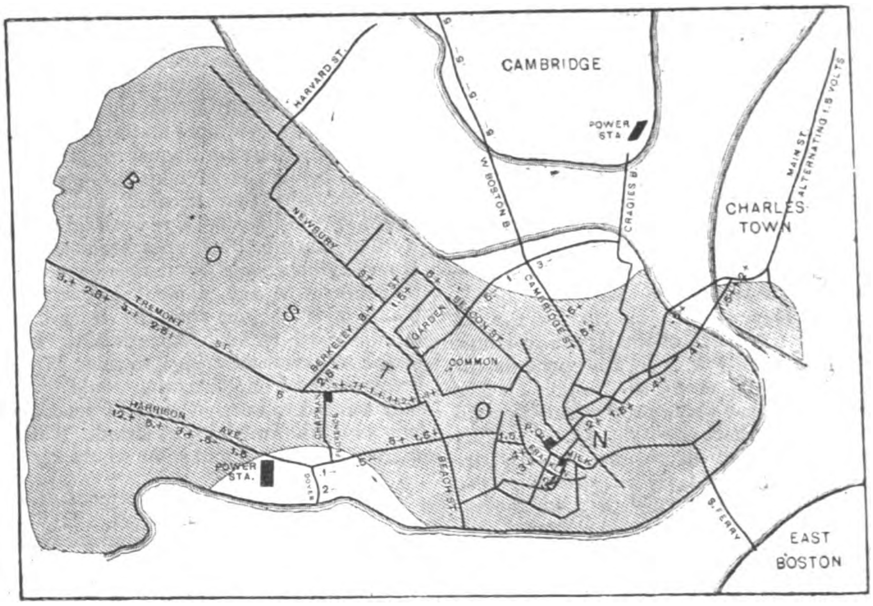

Fig. 3.—Showing where corrosion was going on when first brought to notice.

lead covering of a cable (No. 208), resting upon the ground in manhole chamber No. 76, located at the corner of Berkeley and Newbury streets, was found eaten entirely through at the point of contact with the earth. I then felt certain the cable had been destroyed by the action of the current. With Mr. W. I. Towne, my assistant, I proceeded to prove the theory. We took measurements between the cable and the earth, the cable having been we connected by a wire to cable No. 208, which had been damaged by electrolysis. (It should be understood that the damaged cable had been repaired, and removed from the bottom of the chamber). Fig. 2 shows the arrangement of this experiment. At the end of six weeks, the pieces of cable were removed and examined. The one which had been connected with cable No. 208, was deeply pitted*, while the other piece was free from corrosion, and these

* Abstract of a Paper read before the American Institute of Electrical Engineers.

* The plumbers of Omaha, Neb. apply the name of "small-pox pipe" to that pitted by electrolysis.

Digitized by Google

experiments, with several others of minor importance, satisfied all who were interested, that electrolytic action was destroying cables, and probably gas and water pipes.

It next became necessary to prove to the electrician of the railway company, that the current causing electrolysis was from the railway system, and not from a leak in the Edison or some other electric lighting system. Measurements were made between the cables in all manholes and the earth near the cables, for voltage and direction of current. It was found that within a radius of about 2,000ft. from the Albany-street power-house, cables were negative to the earth, ranging from zero to 2 volts, and that outside of this neutral line, they were positive to the earth from zero to 12

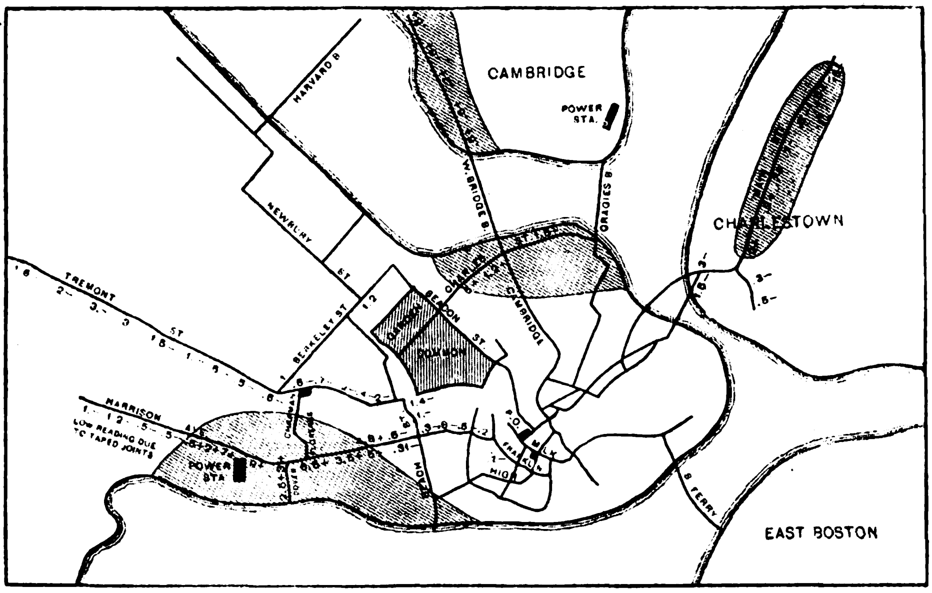

FIG. 7.—Condition after current was reversed by West End Company.

volts. This condition prevailed until a point was reached near the East Cambridge power-house, when they again passed a neutral line and became more and more negative as that power-house was approached. The same conditions were found as the Allston railway power-house was approached. On obtaining sufficient data, maps were drawn, showing voltage between cables and earth throughout all sections of the city. This is shown in map (Fig. 3). In addition to the figures placed beside the several routes of cable conduits, showing the direction of current and its pressure, we

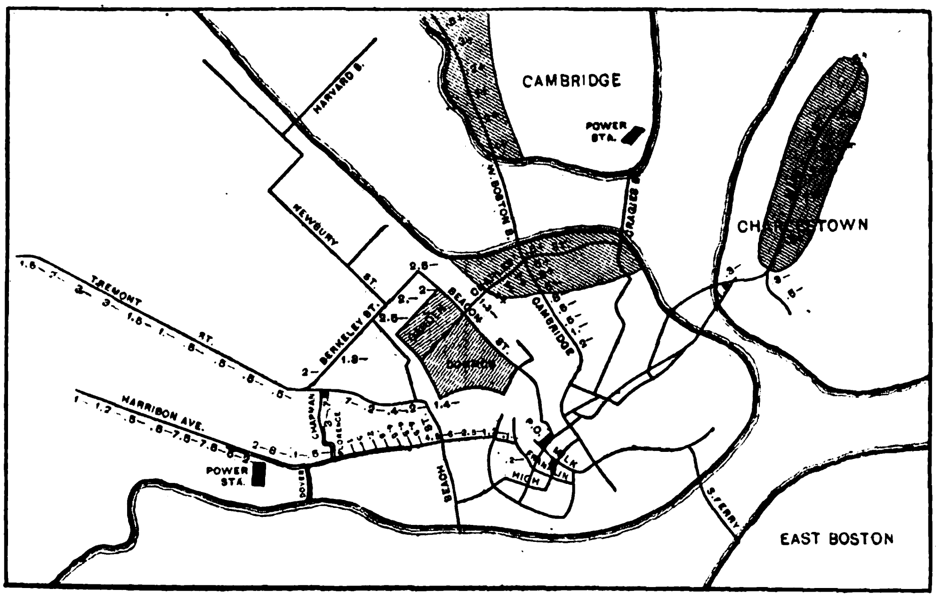

FIG. 8.—Condition, Jan. 4th, after connecting West End ground wire to cables near Power Station.

have shaded, such portion of the map where at that time we found the cables positive to the earth. We may call the shaded portion of the map the danger territory. These potential measurements, though taken for other purposes, incidentally furnished all the proof needed to convince one that the railway power was the source of the troublesome currents.

At the time the map was made, and previously, the railway was operating with the negative pole of the dynamo to the trolley, the positive side being to the rails.

Having outlined our early experience in running down this new trouble, we will next mention some of the proposed and applied remedies. Several conferences were held for the purpose of suggesting and discussing means for preventing the destruction of the cables, at which the officers and experts of both the railway and telephone companies were present, and it should be said, that the railway company in Boston has shown a disposition to adopt any promising plan for overcoming the evil, save, perhaps, the abandonment of the rails and earth as a part of the circuit.

First: It was proposed to remove all cables from the wet bottom and sides of the so-called manholes. It was found very difficult to place and retain cables free from the wet sides, and even could this have been accomplished, the action at the mouth of the ducts, and within them would still have continued. They were, however, all removed from the bottom of the manholes.

Second: It was suggested that the cables might be connected to ground plates in the manholes, and so transfer the electrolytic action to these plates, and thus save the cables. This experiment was tried on an extended scale, but though many ground plates having a surface of several square feet each, were connected with the cables over a large portion of the city, it was found that voltmeter readings taken between the cables and a point on the earth a short distance removed from the ground plate in any manhole, gave nearly the same pressure as before the ground plates were connected. In some cases, the voltage between the cables and the earth was reduced 25 per cent.; in many others, no noticeable reduction was made. The ground plates were constructed from pieces of old lead cable, 6 to 10ft. in length and embedded in the wet earth at the bottom of the manholes. It was evident from this

Digitized by Google

test, that ordinary ground plates would not prove of material advantage for protecting the cables.

Third: Prof. Elihu Thomson suggested, among other possible remedies, the placing of motor generators at different points along the railway line, wherever the cables and pipes are found to be in danger, the motor generators to be operated by the railway power current; the secondary current developed by these generators to be utilised to lower the potential in the cables and pipes to zero, with respect to the surrounding earth or rails. The suggestion included means for automatically starting and stopping the generators, as cables might become positive or negative to the rails. The motor generators would, so to speak, pump the current out of the cables and force it into the rails whenever the potential of the former should rise above zero. Fig. 4 illustrates this suggestion. This plan has not yet been put into operation so far as I am aware.

Fourth: Insulating the cables and pipes from the earth was proposed. As some of the worst cases of corrosion of cables by electrolysis occurred where they were painted with asphalt, taped, painted again, and finally covered again with a heavy braiding also

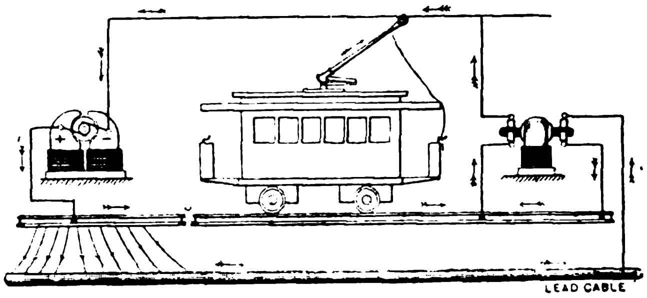

Fig. 4.

saturated with asphalt, it was apparent that to insulate cables sufficiently to protect them would be difficult and expensive, if indeed practically possible. I show specimens of corrosion of cables which had been treated with asphalt, tape and braiding. To protect water and gas pipes by a sufficient insulating jacket was seen at once to be impracticable.

Fifth: Breaking the metallic continuity of the cable sheath and pipes was proposed. From the fact that severe action is frequently found in comparatively isolated spots, where cables and pipes cross each other or pass near or across the rails, it follows that any system of breaking the metallic continuity, would have to be studied with reference to the entire complicated system of pipes, cables and rails ramifying through the streets of a city. There would also be a difference of potential between the several sections of cable or pipe, severed metallically, tending to cause electrolysis at one end of each section, as illustrated in Fig. 5. In case of water pipes, treated in this manner, the action might be expected on the interior as well as on the exterior.

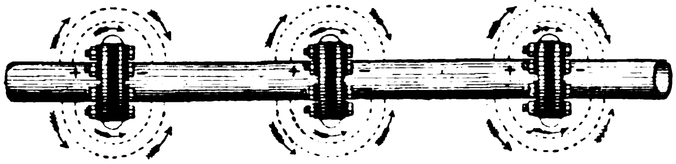

Fig. 5.

There appears to be some evidence of such an action as this in gas and water pipes where the electrical continuity is partially broken by leaded joints. Fig. 6 shows an iron service pipe from the Cambridge gas system. It will be noticed that the action is most severe at points immediately on either side of the coupling. The reason the corrosion appears on both sides of the coupling in this case is not clear; it may be due to reversal of current on the railway system. We have observed other specimens similar to this, which may tend to show that for currents of low pressure, the resistance of joints materially affects the results. I will again refer to this question in connection with potential differences in water mains.

Sixth: My assistant, Mr. Towne, suggested that the railway current might be so frequently alternated as possibly to prevent serious action on the pipes and cables. It seemed possible to reverse it once each 24 hours, at a given time in the night when the load is comparatively light. To do this in a large system involving several power stations would require either a loss of current for a few minutes in order to guard against one station reversing before some other had opened or reversed its current, or would require some electrical system connecting the several stations together, and operating the reversing apparatus simultaneously. We concluded it would be very difficult, if indeed at all practicable, to reverse such heavy currents during regular traffic. We then made a reversing experiment, giving 24 hour periods between each alternation, but found at the end of two weeks, to our sorrow, that the plates subjected to the action of the current were seriously electrolysed. It seemed useless to pursue this line of work further at that time.

Seventh: At about this stage in the study of the problem, Mr. Fred. S. Pearson, then engineer of the West End Street Railway Company, made two suggestions which, though separate in themselves, and presented at different dates, yet carried out in conjunction have proved exceedingly helpful in overcoming the difficulty, at least so far as relates to telephone cables. It occurred to Mr. Pearson, first, that if the railway current should be reversed so that the positive pole would be connected with the trolley, the danger of electrolysis would be removed from the greater and more scattered

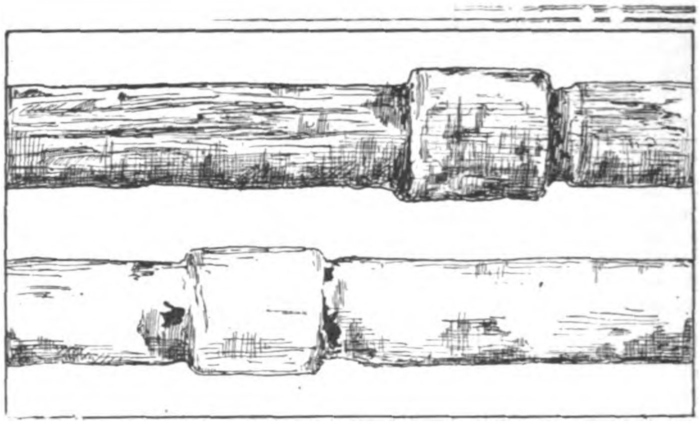

Fig. 6

portions of the city, and be brought near the power stations, where it possibly could be more easily dealt with. This reversal was made, and the expected potential changes between cables and earth followed. Fig. 7 is a map of Boston, showing the condition after the reversal of current. The shaded or dangerous portions in this map correspond to the white or safe districts in the map, shown in the first of this Paper (Fig. 3), the only variation being that, by the reversal, the neutral or zero line was thrown out a little further from the Albany-street power-house than it was located before. It was also noted that the cables near the power-house which had been from one to two volts negative to earth before the change of current, were now one to nine volts positive to earth, that is, they were raised higher above zero than they had been below zero prior to the reversal.

Mr. Pearson next suggested the plan of running out large copper conductors from the negative side of the dynamo, and extending them through the dangerous district, connecting them at frequent intervals to the cables. On the principle involved in Prof. Thom-

Fig. 9

son's motor generators, this low resistance conductor connected directly to the dynamo, was to pump the current from the cables and so prevent its passage into or through the moist earth. Some of us were sceptical as to the completeness of this proposed remedy. It seemed possible that even with a such a good return conductor, some of the current might still pass into and through the earth. Voltage measurements, however, at once dispelled the doubts, for we found that the cables measuring nine volts positive to earth, gave a reading of 22 positive to the return conductor; that is, the return wire as relating to the cables, was at all points, more negative than the earth (if we may be allowed the expression). The return conductors were made up of a large number of No. 18 copper wires formed into cables about one inch in diameter, known as conductors of 500,000 circular mils. These conductors were extended in each direction from Albany-street power-house entirely through this dangerous district, its longest section being about 4,300ft. The cables in every manhole within the district were connected by several No. 12 copper wires to the return conductor and soldered. On first connecting the cables to the return conductor, which took place on December 24, 1892, the current was sufficient to melt several strands of No. 12 wire. A measurement for current flowing in the main return conductor which was used for relieving the cables only, gave about 500 amperes.

Digitized by Google

The map, Fig. 8, illustrates the condition after the installation of the return conductor at the Albany-street station. The danger patch which existed in that locality is now removed, and the cables are all negative to earth. The remaining danger patches were corrected by taking similar means of reaching the East Cambridge power-house. In treating this latter case, many measurements were made to determine whether or not the railway return wires put up to take the current in a measure from the tracks would answer for a return for the cables, instead of using a special return conductor, as had been employed at the Albany-street district. It was found that they would not answer, since the potential of these track return wires varied constantly and was frequently above that of the earth.

The cables on the Boston side of the draw of West Boston bridge, proved to be positive to both the rail and the water, while on the other side of the narrow draw the opposite condition existed, showing at once that it was unsafe to assume any neutral lines or potential difference without making measurements to determine the absolute facts.

So far, this Paper has dealt particularly with the subject of protection of lead-covered cables. It might be inferred that water and gas pipes can be treated in precisely the same manner with the same results, or as water pipes have a much greater sectional area of metal, it might be presumed that simply a connection of such pipes to the dynamo at the power station would be sufficient to bring their potential down to zero throughout the dangerous district. The facts so far coming to our notice would materially modify such inferences, and therefore should find a place here. That iron pipes are as truly subjected to the corrosion as lead need not be stated to the members of this society, but for the benefit of city officials and others who may read the Paper, it should be plainly stated that they are quite as readily destroyed by electrolysis. Fig. 9 is from a photograph of an iron gas pipe taken from Brooklyn, N.Y. The City Engineer of Milwaukee, Mr. G. H. Benzenberg, has kindly sent me a photograph of a 6in. iron water main, badly corroded. It is the best specimen of cast-iron pipe I

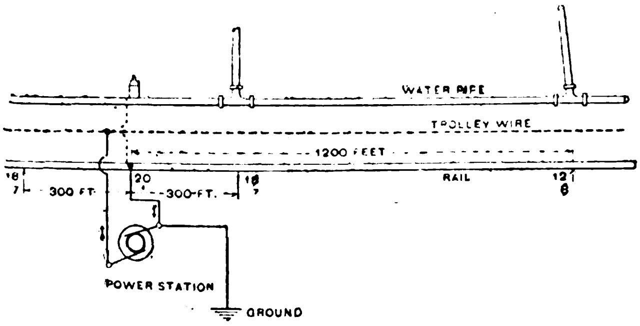

Fig 10.

have been able to obtain, although not the most serious case of corrosion. Mr. Benzenberg writes that the trouble in that city was chiefly noticed upon the six-inch water main extending 100ft. on each side of a point opposite the railway power station. Services entering this main were also destroyed, and all were renewed three times during the past two years. He states further, and I quote his own words, "at other points where power houses were established thereafter, the mains were immediately connected by extra heavy copper wires with the generator; we have had no trouble with them so far." Mr. O. H. Tripp, engineer at Rockland, Me., recently furnished me with a specimen of wrought-iron pipe destroyed in five months; the fact is of special interest as it comes from a city having but a small railway system. In Boston there have been water as well as gas-service pipes corroded through by electrolysis. I have not learned of any mains having burst from this cause. Measurements of water pipes in the city indicate they are still in danger, notwithstanding several thoroughly-made connections with the pipes at the power station; the same is true in Cambridge, Mass. This leads me to call attention to an interesting series of inquiries.

The engineer of the Water Board at Rochester, N.Y., suggested to me a short time ago, while looking into the question of electrolytic action upon the pipes in that city, that possibly there might be sufficient resistance in the joints of the water mains to cause an action upon the lead ring which forms the connection between sections of pipe. He stated that not unfrequently there is found a film of moisture between the pipe and this lead ring, and as the pipes are coated with a preparation of tar or asphalt on both the inner and outer surfaces before they are laid, there might be a poor electrical connection. Without having made any inquiries or tests upon this point, it seems to me probable that the careful caulking which is given these lead rings, would form in some portion of each joint a good electrical connection; that is, one of very low resistance. Recent measurements, however, made in Boston, and others made in Albany, during the latter part of March, this year, convince me that there is a very appreciable resistance in such joints.

Fig. 10 will illustrate the conditions at Albany. We found the negative side of the dynamo to be connected with the rails and with ground plates in old wells; no connection had been made with water or other pipes. Directly in front of the power station the voltmeter indicated a pressure of 20 volts between water pipe (an 8in. cast-iron pipe) and the rail, the pipe being positive. A reading taken about 300ft. in either direction, up or down the street, indicated about 18 volts. At a point 1,200ft. north, the reading was lowered to 12 volts. We then connected the rail side of the dynamo to the street hydrant and took new readings, finding 1 volt at the station, 7 volts at 300ft. distant, the same south, and 8 volts at a point 1,200ft. north. These measurements, with similar indications in Boston, show plainly that there is a very appreciable resistance in the water-main joints. At the same time the measurements give fair evidence that the difference of voltage between any two sections of water pipe is very small. The interested parties at Albany have kindly consented to allow any facts or figures obtained there in reference to this subject to be placed in this Paper. It is proposed at Albany to extend large wires through the dangerous district, one wire for each system of pipes, connecting the pipes to them at frequent intervals.

It is probable that the remedy which has been applied to telephone cables in some cities has been the more positive from the very failure, so far, to thoroughly protect the other systems of pipes against electrolytic action. The cables are connected by a large wire to the dynamo, while water pipes are not so treated. Therefore, the current which enters the water pipes at points outside the danger district passes to the neighbourhood of the power station, and, in leaving them there, raises the potential of the earth about the cables. In other words, the current flows from the water pipes to the ground, and thence to the cables in order to reach the dynamo. Connecting any one system of pipes to the dynamo will, in a measure, protect other systems of pipes, but connecting all systems reduces the certainty or margin of certainty of protection to any one system. When all cables and pipes in the danger district are connected by sufficiently large conductors to drain them, a careful adjustment in resistance in these several conductors may be found necessary in order to insure a balance between the several systems of pipes. It may lead to the necessity of reducing the carrying capacity of the conductor returning to the dynamo from the rails themselves.

The question has already risen, and it doubtless will be repeated here—"How small a difference of potential between pipe and earth will cause electrolytic action?" In reply to this, it may be stated that some of the worst cases of corrosion in Boston have occurred where the difference was but one and one-half volts. Mr. A. T. Wells, of Chicago, in describing to me an examination of some of the first cases in Cincinnati, states that the "difference of potential between the cables and the rail, was never more than one-half, and usually less than one-quarter volt." Such a difference between cable and rail would mean a much less difference between cable and earth, where electrolysis takes place. Mr. John C. Lee, of Boston, has experimentally caused the corrosion on lead and iron by a difference of potential of $\frac{1}{100}$ volt.

These facts certainly indicate that but a very small pressure is necessary to produce the action, and should dispel the numerous statements that well bonded rails or a large amount of rail return wires will alone overcome the trouble. In some cities, where electrolysis is in progress to-day, the return copper nearly equals that of the trolley and feed wire system. We cannot force the current to take one path exclusively when others are open to it.

The facts given above, with others similar, though not enumerated, lead me to these conclusions:

1st. All single trolley railways employing the rails as a portion of the circuit, cause electrolytic action and consequent corrosion of pipes in their immediate vicinity, unless special provision is made to prevent it.

2nd. A fraction of a volt difference of potential between pipes and the damp earth surrounding them is sufficient to induce the action.

3rd. Bonding of rails, or providing a metallic return conductor equal in sectional area and conductivity to the outgoing wires, is insufficient to wholly prevent damage to pipes.

4th. Insulating pipes sufficiently to prevent the trouble is impracticable.

5th. Breaking the metallic continuity of pipes at sufficiently frequent intervals is impracticable.

6th. It is advisable to connect the positive pole of the dynamo to the trolley lines.

7th. A large conductor extending from the grounded side of the dynamo, entirely through the danger territory and connected at every few hundred feet to such pipes as are in danger, will usually ensure their protection.

8th. It is better to use a separate conductor for each set of pipes to be protected.

Digitized by Google

9th. Connection only at the power station to water or gas pipes will not ensure their safety.

10th. Connection between the pipes and rail, or rail return wires, outside of the danger district, should be carefully avoided.

11th. Frequent voltage measurements between pipes and earth should be obtained, and such changes in return conductors made, as the measurements indicate.

In closing this somewhat rambling Paper, I can do no better than use words which will remind you of Patrick Henry; "eternal vigilance" will be the "price" of pipes and cables where conditions favourable to electrolysis exist.

LEGAL INTELLIGENCE.

Wise v. Metropolitan Electric Supply Company (Limited).

On Friday morning, April 27th, Mr. BEALE, Q.C., continuing his argument for the defendants, said they had shown that they had exercised such discretion as ought to have been exercised, with their knowledge of the nature of the works, in selecting the site. They put the works on the site of some old stables, and consulted the agent of Lord Portman, as well as the Vestry, and no objection was raised upon the ground that it was not a proper site. They had not shown negligence in choosing the site or in the construction of the works, there had been no disposition to economise at the risk of nuisance, and, in fact, they had done everything they possibly could to prevent a nuisance. It was suggested in the course of cross-examination that they might stop the nuisance by putting up more engines on another site. They were asked whether they had not room for more engines at Paddington, without regard to the area covered from that station. How did they know, if they they did remove to Paddington, that they would not be involved in the same difficulty they were now under, and that other people would not complain in the same way that the plaintiffs in this case were now complaining?

Mr. VERNON SMITH followed on the same side, submitting that it was rather a case for damages for injury to business than for an injunction. Looking to the evidence, he did not think it was proved that the plaintiffs suffered very serious loss in consequence of the noise and vibration; some customers, no doubt, did not return, but most of the plaintiffs had said they still let their rooms to some extent. Therefore, such loss as they had sustained was a matter which could be met by damages, and he asked his lordship to regard the balance of convenience and inconvenience in the case, by giving the plaintiffs their remedy through the award of damages, and not by granting an injunction.

Mr. GRAHAM HASTINGS, Q.C., replied for the plaintiffs. He submitted that they ought to have damages, and they ought to have an injunction. Having read the cases bearing upon the point as to what constituted a nuisance, notably the definition of Lord Selborne in Fleming v. Hyslop, "whatever causes material discomfort and annoyance for the ordinary purposes of life," counsel argued that there was distinct evidence of nuisance, and also of loss of business, and in one case loss of health in consequence. He asked for an injunction, and that it should not be suspended for any long period, in view of the fact that his clients were still sustaining injury from the continuance of the vibration.

JUDGMENT.

Mr. JUSTICE STIRLING, in giving judgment, said this was an action brought by five plaintiffs who were tenants and occupiers of houses in Manchester-street, Manchester-square, against the Metropolitan Electric Supply Company, who had erected works for the supply of electric lighting in the immediate neighbourhood of the plaintiffs' houses, and it was sought to restrain the defendants from carrying on their business in such a way as to cause a nuisance to the plaintiffs by three different modes, namely, vibration, noise, and by causing smoke and smuts. The defences which were put forward by the Company were twofold: first, it was said that they did not carry on their business in such a way as to cause an actionable nuisance to the plaintiffs; and secondly, that even if they did, the remedy of the plaintiffs was by compensation under Section 17 of the Electric Lighting Act, and not by way of injunction and damage in an action of this sort. With reference to the second of these points, he considered it unnecessary for him to go into the subject, because it had so happened that, this case having been commenced last sittings, and there being no time to prosecute it to a termination, in the meantime the same point had been raised upon the same Acts, and practically the same Order before Mr. Justice Kekewich, in a case which he heard at the commencement of these sittings, and which was decided a few days ago. He (Mr. Justice Kekewitch) had considered fully in his judgment the legal question, he had dealt specifically in that judgment with most of the substantial points which were raised by Sir Richard Webster, and if there were a few points which were not touched upon, it did not seem to him that they would have affected the conclusion at which the learned judge arrived. Therefore, it seemed to him that it would not be right that he should enter into the question again, and he should proceed on the basis of the conclusion at which the learned judge arrived on the question of law. He, therefore started with this assumption, that the defendants were not entitled to carry on their works in such a way as to cause a nuisance to their neighbours; and starting from that point there were two points which he had to consider, first of all, whether a nuisance in the legal sense was caused by the works of the defendants, and secondly, if so, what was the remedy of the plaintiffs in respect of it. He had before him the correspondence which had passed between the plaintiffs and the officers of the Company, and he found that so early as January 13, 1890, Mr. Grant, one of the plaintiffs, wrote to the Company complaining of a nuisance by reason of the vibration. Then in February, 1891, Mr. Barrell wrote to Mr. Bailey also complaining of the vibration. Notwithstanding these letters, Mr. Bailey appeared to have been of the opinion that there was nothing in the complaints, and he stated very candidly in the witness-box that it was not until October, 1892, that he began to believe that there was anything in them. Having at last, after constant complaints, come to the conclusion that they had some foundation, he set to work to investigate the subject, and he stated that about that time he reported to his Board, and was instructed to take every possible means to overcome the cause of complaint. The result of Mr. Bailey's inquiries was that he discovered that the works were not situated on absolutely solid ground. It was found that somewhere about from 10 to 12ft. below the floor of the engine-room there was a stratum which was variously described by witnesses as spongy clay or mud, or saponaceous clay. That stratum extended to a depth of 23ft., and it was discovered that at all events when that stratum became charged with water it was of an elastic nature, and that the engines and alternators which were employed in the manufacture of the electrical supply transmitted their vibrations through the solid bed of brickwork and concrete on which they were placed to this lower stratum, and that then they were propagated to the houses of those who were now complaining. The plan which he (Mr. Bailey) suggested, and which was adopted, under the advice of eminent engineers, to remedy this effect, was to place underneath the solid bed of brickwork and concrete columns reaching down to the solid London clay, some 23ft. below the termination of the uppermost stratum, which was supposed to be solid, and on which the brickwork and concrete rested. These were cast-iron columns, filled with concrete, and one was placed between every two engines. The works were completed in November of last year, and it was stated that they cost somewhere about £2,000. But, unfortunately, it had turned out that even this did not put an end to the vibration. The question arose, What was the reason of that? and the answer which was given by the defendants' witnesses (Mr. Bailey, Prof. Kennedy, and Dr. Hopkinson) was, that although what might be termed the vertical vibrations had been stopped by means of those pillars, the horizontal motion was not stopped; that was to say, those pillars, solid though they were, did yield to a certain extent in a horizontal direction, moving, as an inverted pendulum would do, from the bottom of the column, the bottom of the column being fixed, the top gave way to a certain extent, and horizontal vibrations were still transmitted through the stratum of spongy clay. Now the further question arose, Could this be remedied? The witnesses whom he had mentioned agreed that probably it could. All of them very properly admitted that the problem they had to solve was a new one, and they could not speak with absolute certainty on such a question, but if they were correct in the view they had entertained as to the origin of the vibrations which still existed, then they would in all probability be stopped by placing at the top of the columns slanting struts in such a way as to stop that horizontal vibration. A pair of such struts had been placed in position; but they were not absolutely completed or effectively connected with the columns at the present time, but it was said that they would be completed in a short time. It was further proposed, if that were not found sufficient to absolutely stop the vibration, to put in further struts at different points. But the important point to be considered was this, that it was admitted on all hands—defendants' witnesses did not dispute it—that vibration did exist in those houses, and it might be taken as a fair conclusion from the evidence that there was a substantial amount of vibration existing in those houses due to the working of defendants' engines. All the scientific witnesses gave their evidence with the greatest possible fairness—and among them he included Mr. Bailey—and he did not propose to go through that part of the evidence, as to which there was no question. But did this vibration constitute a nuisance? That was the next question he had to decide: and the test to be applied was that suggested by Vice-Chancellor Knight-Bruce in Walter v. Selfe, and by Lord Selborne in the House of Lords, did it cause material discomfort or annoyance for the ordinary purposes of life to those houses, and to the business of lodging-house keepers carried on there? In beginning to consider the evidence upon this point, he would remark that the question was put to Mr. Bailey as to whether he considered these complaints were in any way unfounded, and although he thought some of the statements were slightly coloured and exaggerated he did not seriously dispute the general accuracy of the evidence. His lordship then read portions of his notes of the evidence given by the several plaintiffs, and by their lodgers, remarking that whilst they spoke very forcibly as to the vibration, which was the first ground of complaint put forward, and evidently felt it to be a real grievance, he was not much impressed with the manner in which they gave their evidence as to noise, which seemed to be rather an appendix to the vibration, as sometimes a complaint about air was added to a complaint about light. But as to the vibration, it did seem to him that the witnesses gave their evidence with great moderation, and without any serious exaggeration. It might be that there was a little colour here and there, but substantially the case of the plaintiffs as to the interference with the comfort of the houses as the effect of the vibration was made out. He could not come to the same conclusion as regards either the noise or the smuts, which he did not think was a serious part of the nuisance. He accepted entirely the statement made by Mr. Bailey that during the coal strike they were unable to get the proper and usual coal, and were compelled to burn coal of an inferior quality, which did produce a certain amount of smoke, but there was certainly no case made out for an injunction upon this head, nor did he think there was any case made out as to damages. But that was a small part of the case, and he did not think any serious expense had been incurred in consequence of the mention of noise and smuts. It did seem to him that there was substantial interference with the houses

Digitized by Google

and businesses of lodging-house keepers carried on by the plaintiffs, and that that ought to be ground for an injunction, and also an inquiry as to damages. But it was said on behalf of the Company that if an injunction were granted it ought not to be put in immediate operation. He was entirely of that opinion. He thought the Company had been unfortunate. It was not necessary for him in the view he had taken to go into the question of negligence, and he should say nothing upon that, but he certainly thought that since October, 1892, when the attention of the engineer was first seriously directed to the matter, they had done their very best to remove all ground for complaint on the part of the plaintiffs, and if they had not succeeded up to the present time it was not attributable to any negligence on their part, but to the fact that they had had to deal for the first time with a very difficult question. He thought the Company ought to have a fair opportunity of completing the works upon which they were now engaged, and which there was reasonable hope would entirely prevent the nuisance; and they certainly ought to have a reasonable time allowed them for that purpose. Having regard to the difficulty of the subject, he thought it would be a fair thing to suspend the operation of the injunction for three months at least, and that would give them an opportunity of bringing the matter before the Court before the Long Vacation if, unfortunately, the efforts of the engineers did not meet with success. He proposed, therefore, to grant an injunction as regards vibration only, an inquiry as to damages on that subject, and to suspend the operation of the injunction for three months.

Mr. GRAHAM HASTINGS asked for costs on the higher scale, as the questions dealt with were difficult ones.

Mr. JUSTICE STIRLING said the question which the advisers of the defendants had to determine was a difficult one, but he did not think the question before the Court was such as to require costs on the higher scale.

Muirhead v. The Commercial Cable Company.

Judgment was given in this action on Saturday last. A full report of the case will be found in our issues of March 9th and 16th last.

JUDGMENT.

Mr. JUSTICE KENNEDY: This is an action brought by John Muirhead, Alexander Muirhead, and Herbert Arnand Taylor, to recover from the defendants, the Commercial Cable Company, the sum of £3,565. 1s. 6d. under an agreement in writing, dated January 2, 1884. At the date of the agreement the plaintiffs were the holders of certain English, Canadian, French, and American patents for apparatus to be used in duplex telegraphy. The defendant Company were about to lay and work certain submarine telegraphic cables, and the purpose of the agreement was to secure to the Company, in the establishment and working of their cables, the use of the patented apparatus, and of improvements in that apparatus. By the terms of the agreement, in consideration of the payment to the plaintiffs during the continuance of the agreement of certain specified royalties, which were to be calculated and assessed in the manner therein prescribed, and to be paid quarterly, the plaintiffs granted to the defendant Company the use of their patented apparatus with its improvements, in the form and to the extent which is set out in the agreement. The first article is the only part of the document in the precise language of which there is any importance as regards the decision of this action. The article runs thus:—"The inventors grant to the Company the right to apply their said patented duplex apparatus to the above-named cables. This grant is made for the whole period during which the patents shall last. The inventors bind themselves, moreover, at the request of the Company to give them during the continuance of this agreement the benefit of all improvements and modifications which they may discover in the said duplex apparatus, whether they be or be not by letters patent, or otherwise legally protected, but in that case the present contract shall be prolonged for a period equal to the term of any new patents that may be taken out." For the purposes of this case it may be taken that this agreement was until July 1, 1891, carried out by both plaintiffs and defendants. But the quarterly payments which would, if the agreement was still in force, have become due on September 29th and December 25, 1891, have not been paid, and this action was instituted by the plaintiffs to recover them. If the right to them exists, there is now no dispute as to the figures. But the action has pecuniarily an importance which goes far beyond these figures, for if the plaintiffs are entitled to succeed as to these two payments, it follows that they are entitled to similar quarterly payments for several succeeding years also.

The issue which is raised in the action may be stated in a single sentence, and it is this—Was the Patent No. 234,490 granted to the plaintiff, Alexander Muirhead, on November 16, 1880, in the United States of America, a patent which, in the language of that article of the agreement which I have just quoted, "was lasting" after July 1, 1891. The plaintiffs contend that it was. If it was not, the defendants are entitled to judgment in their favour. Simple, however, as the statement of the issue is, the determination of it involves some important questions of law and some important and, in my judgment, more difficult questions of fact of a scientific and highly technical character, the trial of which occupied several days. The controversy arises in the following manner:—The patent to which I have referred was, as I have said, granted by the Patent Office of the United States on Nov. 16, 1880. The grant is expressed to be a grant of letters patent for the term of 17 years from that date. *Primâ facie*, therefore, it would last until Nov. 16, 1897, but being a United States patent, it is governed by the law of the United States. It is part of the statute law of those States that "Every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one at the same time, with the one having the shortest term, and in no case shall it be in force more than 17 years." This statutory provision is repeated in the 29th of the Rules of Practice of the United States Patent Office (revised September, 1880), which are established under statutory authority by the Commissioner of Patents, subject to the approval of the Secretary of the Interior; and in the 162nd Rule it is further laid down *inter alia* that "Every patent will contain a short title of the invention or discovery, indicating its nature and object, and a grant to the patentee, his heirs and assigns for the term of 17 years of the exclusive right to make, use, and vend the invention or discovery throughout the United States and the territories thereof. But if the invention shall have been previously patented abroad, the term of the patent will expire with the term of the foreign patent." It has been in my view settled by judicial decision in the Courts of the United States, in reference to those provisions, that although a United States patent has not upon its face been limited, but contains an express grant of the patent rights for the full term of 17 years, nevertheless, by operation of law, if the invention has, in fact, been previously patented abroad, and the foreign patent expires before the 17 years term has run out, the United States patent expires at the same time.

It is also, in my judgment, settled law that the United States statutes are not to be construed as invalidating *ab initio* a patent wherein, although it is for an invention previously patented abroad, the grant is not limited as it ought to have been, but runs for the full term of 17 years. The statute is to be construed simply as controlling the effect or duration of the grant. In other words, the grant is a valid grant, but is good only for the shorter term, and expires at the expiration of the foreign patent. It is, in my view, further, the law of the United States, that in such a case as that to which I have just referred, where the grant has wrongly been made for a term exceeding the duration of the earlier foreign patent, it is not necessary, in order to terminate the rights of the patentee, and to prevent the exercise by him of the privileges of the grant after the period to which the grant ought to have been limited, that any judicial proceedings should be taken for the purpose. By operation of law, that is, of the Statute which I have cited, the United States patent is extinguished and expires, notwithstanding the terms of the grant, when the foreign patent expires.

This being the state of the American law as to patents, the defence of the defendants to the plaintiffs' claim in this action is, that the invention for which the United States patent of November, 1880, was granted was, in the words of the Statute which I have cited, an invention "which had been previously patented in a foreign country" (the "foreign patent" in this case was the English patent granted in 1876, No. 2,564), and that the foreign patent expired not later, at any rate, than July 1, 1891; that, consequently, the United States Patent of November 16, 1880, although containing a grant for 17 years from that date, also expired at the same time, and therefore, as after July 1, 1891, there was no patent which was "lasting" within the meaning of the agreement between the parties, the obligation of the defendants to pay royalties then ceased.

In reply to this defence, the plaintiffs raise two sets of contentions, the first of a purely legal character; the second resting partly on law and partly on fact, and based upon the construction of the English and American patents, and the inferences to be drawn from the scientific evidence which was adduced before me to explain the terms and the subject matter of the various patents.

First as to the law. The plaintiffs' points on this head resolve themselves, I think, into four. First, they say that whilst they do not dispute that as between the patentee and a party charged with infringing the patent, the alleged infringer may, according to American law, succeed by proving that the American patent has expired because of the expiration of a prior foreign patent granted for the same invention, although the duration of the American patent has not been limited, as it ought to have been, upon its face, to the duration of the foreign patent, yet that this line of defence is not open to a licensee as against his licensor. The plaintiffs contend that such a defence in truth involves an attack upon the validity of the patent which is expressed to be granted for the full term. I am unable to take this view. It appears to me that all that the defendants seek to do is to do that which is permissible to a licensee as against his licensor, just as it is permissible to a lessee against his lessor, that is, to show that his right, originally good, has expired. The American law does not, upon proof that the invention which has been patented in the United States has been the subject of a prior foreign patent, avoid the grant *ab initio*, but treats the duration of the grant as limited to the life of the foreign patent, just as if that limitation had been originally written into the patent. The term is treated as if it had been expressed from the first, as it ought to have been. But then the plaintiffs in this case lay stress upon the particular terms of this agreement. The obligation upon the defendants is to continue, according to that agreement, "for the whole period during which the patents shall last." Mr. Finlay argued that this means "as long as they last on the face of them without attack," and that the expression is merely another way of suggesting what he called the "face-term" of the patent, that is to say, 17 years. I cannot so interpret the agreement. I read it as meaning the whole period for which the patent lasts as a patent according to the law of the United States. When it lasts no longer as such, it appears to me that defendants' obligation also ceases. I cannot see any estoppel to prevent the defendants showing that the true effect of the patent according to the law of the State which made it, is a grant which, in the circumstances alleged, gives a term of 14 and not of 17 years. There remain two other points of law raised by the plaintiffs' counsel in argument. It is pointed out correctly enough that the law of the United States only applies to the case of an invention patented in the United States where the invention has been previously patented in a foreign country by the American patentee, or by some person with his knowledge or consent. In this case the American patentee is Mr. Alexander Muirhead, and the English patent in question, the patent of 1876, is granted to his brother,

Digitized by Google

Mr. John Muirhead, the invention being stated to be "partly a communication from abroad by Alexander Muirhead residing at Aden." The fair inference which the plaintiffs, who called both the Messrs. Muirhead as witnesses, might have rebutted, if in truth it could be rebutted, appears to me to be that the English patent of 1876 was granted for an invention, whatever it was, with Mr. Alexander Muirhead's knowledge and consent; and if that be so, then I think that the American law would apply, if the English patent is found in fact to include the thing which was patented in the United States in 1880. Lastly, I was pressed to hold that I could not, sitting here, find that the United States patent had expired without proof of a decision in a United States Court to that effect, and in the absence of such a decision, the point which the defendants raise as to the expiration of the 1880 patent, ought to be treated as a point not open to them. It was put by the learned counsel for the plaintiffs rather on the ground of convenience He suggested a hardship upon the patentee, on the ground that he could not, when sued in this Court, as he might perhaps have done if sued in the United States, place himself in safety as regards the allegation of identity of the 1876 and 1880 patents by disclaiming part of the latter patent. He also pointed out the possibility and the undesirableness of a conflict of judicial decisions—an American Court holding the patent to be good, whilst the English Court had held differently. It appears to me that I could not properly rule that the defendants' line of defence is inadmissible on any such grounds. The action is brought on the agreement. It is an action properly brought in the English Court. By Article 9 of the agreement it is provided that "These presents are to be read and construed as an English contract and all questions arising thereout shall be determined by a competent English tribunal to the jurisdiction of which the parties hereto bind themselves beforehand to submit." What is the question on the agreement? It is the question whether an American patent was or was not lasting after a certain date. How could I properly refuse to try that question because it involves matters of the law of the United States relating to patents? It seems to me to be clear that I must deal with this as other questions of foreign law are constantly dealt with in the Courts of this country, upon evidence of that law. I may add that in this case, through the good sense of the parties, the materials for forming my judgment as to the foreign law applicable to this case have been put before me in a most satisfactory and convenient form.

Having thus dwelt with the plaintiffs' contentions in point of law, I come to the consideration of that which appears to me to be the most difficult, as it certainly is the most interesting question in the case—the question of fact to which, during the seven days' trial the greater part of the evidence and the arguments of counsel was directed. Are the defendants right in their contention that Muirhead's American patent of 1880, has, in the language of the American Statute, been granted for an invention which had been previously patented in England in 1876? Unless the defendants are right in this, the defence to this action wholly fails, and the plaintiffs are entitled to my judgment. In order to enable me to form my judgment on this issue, which involves considerations of a scientific and highly technical character, I have had adduced before me on each side a great body of most valuable scientific evidence. I have also had (and I desire to make my acknowledgment of it) very great assistance from all the counsel engaged in the case—assistance which included, amongst other things, the neat and excellent model of the duplex apparatus which was, as I was informed, constructed by Mr. Walter, the junior counsel for the defendants.

The American law applicable to this class of case has been placed before me in a collection of judicial decisions. What are the principles by which, acting upon these decisions, I ought to be guided in the consideration of this case? There are three passages, and three passages only, from the selected judgments to which I think it necessary to refer as laying down principles of law which might be held to be applicable to this case. The first of those occurs in the judgment of Mr. Justice Coxe in the case of the Brush Electric Company *v.* Julien Electric Company and others, decided in the Circuit Court, S. D. New York, March 18, 1890. The principle laid down I believe to be identical with the principle upon which an English Court would act in a similar case. "The law does not favour forfeitures. A patent should never be declared invalid because of the expiration of a foreign patent, if there is doubt about the inventions being the same. The burden is upon the defendants, and the doubt should be resolved in favour of the patent." The second passage to which I propose to refer is one to which my attention was directed by the learned counsel for the defendants. It is that which is laid down by Mr. Justice Bradley in Siemens's Administrator *v.* Sellers, in relation to the case of the American patent containing improvements on the earlier patent. He lays down the law in the following terms:—"It is contended by the counsel of the complainants that the American patent contains improvements which are not exhibited in the English patent, but if this were so it would not help the complainants. The principal invention is in both, and if the American patent contains additional improvements, this fact cannot save the patent from the operation of the law, which is invoked if it is subject to that law at all." The third passage to which I shall refer deals with the test of the identity between the subject-matter of the two patents, which is necessary in order to bring into operation the law upon which the defendants rely. I find that the test is, as one might expect, put in various ways in the American cases which have been brought under my notice, but nowhere I think has it been so fully or satisfactorily stated as in the judgment of Judge Coxe, following, as the learned judge says, the judgment of the Supreme Court in two earlier cases, in the action of the Electric Accumulator Company against the Julien Electrical Company. Applying his language to this case, one may find the proper test of identity in the answer to the following questions:—First, is the principal invention of the American patent of 1880 found in the English patent of 1876? Secondly, is the subject matter of the one the same in all essential particulars as that of the other? In other words, will a structure made pursuant to the English patent of 1876 infringe the American patent of 1880? Thirdly, could both the patents have been granted in America? Fourthly, would a person skilled in the art, after reading the description of the invention covered by the English patent of 1876, be able to construct the apparatus described and claimed in the American apparatus of 1880? It appears to me, and I think that counsel in argument put the same view, that these are the principles deducible from the American decisions which are really relevant to the issue in this case, as to the identity of the patents of 1876 and 1880, and I have kept these principles in view in the careful consideration which I have given to the contents of the patents themselves, and to the scientific evidence adduced at the trial in regard to their terms and subject matter. The claim of the 1880 patent is, in my judgment, a claim of the narrowest kind. It is a claim for a particular combination only affecting, as the patentee alleges, new and useful improvements in duplex telegraphy. There is no claim made for any of the structural elements of the combination outside the combination. Admittedly, all those elements taken separately are old. "My invention," says the patentee in his specification, "relates to duplex telegraphs of the class worked on the bridge or differential system. Its object is more especially to reduce the retardation of the signals, and thereby to increase the speed of transmission of submarine telegraph lines, which ends I attain by certain novel combinations and organisations of old instrumentalities set forth in the claims at the end of this specification." The defendants, in order to succeed in their defence, have to establish that this particular combination of old instrumentalities, the working of which, undoubtedly, produces better results than had ever been obtained before, is to be found in the English patent of 1876. In my judgment they have failed to do so. It is unnecessary for me to recapitulate the parts of the combination. They are enumerated, as the patentee says, in the claim at the end of the specification. I need, in order to make the ground of my judgment clear, only to point out that element of the 1880 combination which, whilst the union of all the elements is necessary in order to attain the result, differentiates in my view the invention claimed in the 1880 patent from any combination which is claimed by the patent of 1876. Put shortly, but I hope accurately, the distinction appears to me to consist in the method and means of adjustment, or, as it is called by some of the expert witnesses, the method and means of procuring and maintaining the necessary balance. By the introduction of that method and means, as I understand the evidence, the patentee has been enabled, whilst possessing the necessary facility for getting and maintaining balance, to do that which for speedy (and speedy means successful) working of duplex submarine telegraphy is all important—the elimination, or, at all events, the reduction to the slightest proportions of resistance in the arms of the bridge. I am satisfied by the evidence of Lord Kelvin, Mr. Bottomley, Prof. Thompson, and Dr. Hopkinson that the introduction of the three-terminal rheostat of low resistance placed at the apex of the arms of the bridge, and, therefore, in such a position as not merely to afford an easy and sufficient means of varying the resistance so as to get the ratio which gives a balance, but also to maintain the sum of the resistances of the two bridge arms constant, is a very important part of the 1880 combination. I do not find any combination containing that element in the patent of 1876. The battery, the key, the receiving instrument and its condenser, and, although the language of the specification is on this point somewhat obscure, the use in connection with these, as in the patent of 1880 of the bridge condenser—all these are, I think, to be found in the 1876 patent. But I do not find there any claim for the employment in combination with these elements of the means and method of adjustment which, as I have said, form, in my judgment, an important part of the combination of 1880. On the contrary, I find there, in the 1876 patent, numerous methods of adjustment of a much more clumsy and complicated nature, and a preference expressed in lines 29—31 of the 1876 specification for an arrangement by which the receiving instrument is connected with the opposite poles of the condensers on the bridge side, which would require the maintenance of a high resistance in the two arms of the bridge, and therefore plainly would be incompatible, as I understand the evidence, with the use of a low-resistance rheostat and the elimination of all resistance from the arms of the bridge, as is effected in the 1880 patent.

It is said, on behalf of the defendants, that, as some method of adjusting the resistances is essential, and the adjustment in the bridge arms was a common, though not a necessary, method in 1876, and a rheostat as a ready means of adjustment was known to electricians in 1876, one ought, looking especially at Figs. 1, 2, and 3 of the 1876 patent, to treat the author of that patent as implied, by including in the combinations which he there claims, the use of a rheostat of the kind, and in the position described in the patent of 1880. I cannot help thinking that such a doctrine of implied claim ought in any case to be applied with the greatest possible caution. The danger of its working injustice to inventors is obvious. In this case, if I regard only the points in the specification of 1876 to which I have referred, I certainly cannot apply it. But the argument against such an implication does not, upon the evidence, rest there. I have to consider the fact that the application of duplex telegraphy to long submarine cables was, in 1876, in its infancy, that improvements in this branch of applied science have been obtained, and can be obtained only by experiment, and that when I am asked to find that any practical electrician of ordinary intelligence—I think that, in using this expression, I am understating the argument of Mr. Moulton—would imply in Fig. 2 of the 1876 patent the adjusting method of 1880 as an adjunct of the apparatus. Not only do eminent experts like Lord Kelvin and Sir Frederick Bramwell depose as a matter of opinion, that they could find no grounds for such an implication, but, in fact, the Messrs. Muirhead, who were not only persons of special skill and knowledge, but who were themselves the authors of the invention of 1876, and Mr. Taylor, who has been working with them in developing and improving duplex submarine telegraphy, were during the

Digitized by Google

four years from 1876 to 1880 unable to find in the patent of 1876 the combination of 1880, and did not even dream, as Mr. Taylor said, of the possibility of such a combination. "We knew," said the same witness, "that resistance in the arms of the bridge meant so much retardation, so much less speed, and we quite recognised that we wanted to reduce this resistance, but we did not know how, because we did not get a balance with the low resistance we could not get a balance without high resistance."

I have come clearly to the conclusion that the combination patented in the United States was a new invention and was not an invention for which the English patent of 1876 had been granted. Tested as according to the principles enunciated in the American cases it ought to be tested, it seems to me that the allegation of the identity of the patents upon which the defence is based has failed. The patent of 1880 was therefore a lasting patent at the dates fixed by the agreement for the payments claimed in this action; and I therefore give judgment for the plaintiffs on the claim with costs.

A discussion took place as to whether or not the plaintiffs were entitled to interest on the amount at 5 per cent. It was finally decided that the question should be mentioned to his lordship on Monday, counsel in the meantime to agree as to the exact amount of such interest, if payable. Execution was stayed for 21 days to consider the question of an appeal. On Monday, on the case being mentioned, Mr. Justice Kennedy said the question involved a considerable sum of money (£3,566. 1s. 5d.), and he was willing to hear the arguments at any time which counsel might agree upon, either during or after the regular hours for sitting. If, therefore, counsel would agree upon an hour and day and let him know, he would meet them in any way he could. The matter then dropped.

CORRESPONDENCE.

THE LIGHTING OF THE VICTORIA EMBANKMENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have been watching the suggestions made for the electric lighting of the Embankment, but I do not recollect having seen any reference to a plan which, to my mind, appears the simplest and best, viz., the removal of one in, say, every 12 or 15 of the trees on either side of the roadway and immediately opposite to one another, and the erection in its stead of a handsome standard to carry a five or six-ampere lamp. This would effectively light the roadway, which I take to be of primary importance, and at the same time preserve, or rather improve, the appearance of the Embankment from the bridges at night.—Yours, &c. BENNETT PELL.

Blackheath, April 28, 1894.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Electric Lighting Committee of the Halifax Corporation invite tenders for the supply and erection of steam pumps, pipes, valves, &c., at the electric lighting works. Particulars can be obtained of Mr. T. P. Wilmshurst, borough electrical engineer, Foundry-street, Halifax, and tenders have to be in to Mr. Keighley Walton, town clerk, by 10 a.m., on Thursday, May 10th.

——— The Brighton Town Council announce in our advertisement columns that they are prepared to receive tenders from persons willing to enter into a contract for the supply of motor-alternators, transformers, meters, &c. Specifications may be obtained from Mr. Francis J. Tillstone, the Town Clerk, to whom tenders must be sent in before 10 a.m. on Wednesday, the 16th inst.

——— The Derby Town Council have accepted tenders for the electric wiring of the Town Hall, the Police Station, the Market Hall, and other public places, the work being shared by Mr. Fletcher, of Burnley, and Messrs. John Davis and Son, of Derby.

TENDERS ACCEPTED.—The Waterloo and City Railway Company (Limited) have received the following tenders for the construction of their line of railway:—

J. Mowlem and Co., London (accepted)	£229,064
Price and Willis	230,835
J. T. Firbank	245,184
W. Scott and Co.	245,555
Pearson and Co.	253,170
Pauling and Elliott	328,114
Perry and Co.	445,829 (!)

The period for completion of contract is, in the case of the successful tender, 2½ years.

TENDERS ACCEPTED.—The Lighting Committee of the Brighton Corporation have received six tenders for the supply and erection of two engines, dynamos, and accessories at the North-road electric lighting works ranging from £6,503 to £5,550, and the tender of Messrs. Crompton and Co. (the lowest sent in) has been recommended for acceptance for the sum of £5,550.

——— The tender of Messrs. Stenner and Co., of Fore-street, Tiverton, has been accepted by Mr. C. D. Harrod for the supply of the plant and apparatus required for the installation of the electric light to his country mansion at Morebath, Devon, at an estimated cost of between £500 and £600.

——— The Worcester Corporation on Tuesday accepted the tender of the Brush Company for laying the necessary mains in certain streets of the city for the amount of £1,861.

——— The Bath City Council have accepted the tender of Messrs. Wyndham and Waters, of Croydon, for the electric wiring of the Municipal Buildings for the sum of £245.

APPOINTMENT.—Mr. Reginald H. T. Drummond, A.M.I.E.E., has been appointed chief electrician at the Madrid station of the Electricity Supply Company for Spain (Limited). Mr. Drummond was formerly at the Bankside station of the City of London Company.

SALE BY AUCTION.—Messrs. Welsby and Bousfield will sell by public auction the whole of the electrical fittings and materials recently used at the Bristol Industrial and Fine Arts Exhibition. The sale takes place on Thursday, May 10, and following days at 12 o'clock. Further particulars are given in our advertisement columns.

——— Messrs. Wheatley Kirk, Price and Goulty issue a preliminary announcement of an important sale of new electrical fittings, plant, &c., which will shortly be sold by public auction.

——— Mr. J. C. Stevens announces in our advertisement columns that he will sell by auction at 38, King-street, Covent Garden, London, W.C., on Wednesday next, at 12:30, a large quantity of electrical apparatus removed from the School of Electrical Engineering, and the stock of the Primary Syndicate.

INSTALLATIONS FOR SALE.—Messrs. Wheatley Kirk, Price and Goulty have for sale cheap several electric light installations, some particulars of which will be found in our advertisement columns.

LIQUIDATION.—Claims against the Trent Gas Engine Company, Limited (in voluntary liquidation), must be sent to Mr. Robert Mellors, King John's-chambers, Nottingham, by May 25th.

——— In the Chancery Division on Wednesday the petition of Mr. A. Dawson and other shareholders for the winding up of the South Staffordshire Tramways Company (Limited) was heard. It was stated that the Company had paid no dividends since 1887, and in April, 1893, a debenture-holders' action was commenced, under which receivers and managers were appointed. The petitioners attributed the condition of the Company to a contract entered into by the Directors with the Electric Construction Company, but it was contended that this contract was very favourable to the tramway company, and, the charges made against the directors having failed, the petition ought to be dismissed. The hearing of the case was not concluded.

DISSOLUTIONS OF PARTNERSHIP.—Mr. J. W. Scott has retired from the firm of Messrs. Girdlestone, Tatham and Co., and the business will be carried on in future by Messrs. J. O. Girdlestone and S. B. Tatham.

——— Messrs. Turvey and Gullette, electrical engineers, 19A, Cowcross-street, London, E.C., have dissolved partnership. Debts will be paid by Mr. W. L. Gullette, who continues the business.

NEW WORKS.—The Hayesmoore Company have opened works for the manufacture of electrical specialities at Union-mews, Union-street, W., the head office remaining at Clapham-road, as hitherto.

MESSRS. W. J. FURSE AND CO.—This Nottingham firm have in hand an installation of the electric light at the new house and museum recently erected by Dr. Mason at Burton-on-Trent, and have just completed orders for putting in the electric light at the leather-dressing works of Messrs. E. Turney and Co. and Messrs. Bayley and Co., of Nottingham. In both cases E.C.C. dynamos and Tangye horizontal steam engines are employed.

MESSRS. ROOTHAAN AND ALEWIJNSE.—This firm have taken into partnership Herr H. Schuurmann, and the business will be carried on in future under the title of Roothaan, Alewijnse and Co. Large show rooms are now opened at the Brussels works.

NATIONAL TELEPHONE COMPANY.—Owing to the ambiguity of a circular issued by this Company, many subscribers to the Metropolitan system were alarmed at the prospect of having their telephone numbers "re-arranged." It would appear, however, that this re-arrangement will only affect about 10 per cent. of the Company's subscribers, which will be a consolation—to those not affected. This alteration is required owing to the necessity that has arisen for concentrating the exchanges, particularly in the E.C. district. Some years ago a number of the smaller E.C. district exchanges were grouped into the East India Avenue Exchange, and it is now proposed to still further concentrate the Company's operations by closing the exchanges at Coleman-street

Digitized by Google

and at East India-avenue, and transferring the greater portion of the subscribers into the extensive exchange now nearing completion above the old Hudson Bay Company's premises in Lime-street, E.C., which accounts for a portion of the subscribers' numbers being changed. Here, in a handsome square room, has been installed apparatus at present capable of accommodating 3,000 subscribers, and which is arranged for an ultimate capacity of over 6,500. The interior and exterior arrangements have been entirely designed and carried out by the Company's officials, and the results of the efforts of the staff will be that the Company will possess an exchange which should prove second to none in efficiency, and second to very few in size, either in Europe or America. We think it will be agreed that when the huge outside structure in Lime-street is completed, great credit will be due to those who have designed and carried out a really imposing example of telephone construction work. The outside installation consists of 39 poles 30ft. in height, and 4½in. in diameter at the base. These poles are capable of carrying 30 arms, with 230 wires on each arm. The poles occupy a circular space of considerable extent, and are strongly erected in octagonal form on iron girders. The Company have been fortunate in securing a building for their operations which is probably one o the best-built structures in the City of London—in fact, there are few buildings even there upon which such an immense weight could be with safety erected. The Exchange will have been about twelve months in hand, and is expected to be complete in about a month. The current required for working the new automatic restoring and locking indicators and for the transmitters is produced by a battery installation consisting of 24 cells of 23-plate L-type E.P.S. accumulators, and these are to be charged by a 1-H.P. nominal Tangye gas engine and a 15-volt Œ C.C. dynamo of 60 amperes capacity at 420 revolutions. A special room has been built for the accumulators on the floor below the operating room. It is calculated that at present about 60 operators will be engaged, and the arrangements made provide excellent accommodation for this large staff. Considerable space has been saved by the use of specially designed switchboards, which also effect a great saving of labour for the operators, who are, in addition, to be supplied with specially designed head and breast gear in place of the existing portable telephone and hanging transmitter. These new instruments are manufactured by Messrs. Ericsson and Co., of Stockholm, and have been tested by the Company's officials with, we understand, every success. We are also informed that a new form of transmitter is to be supplied to subscribers at an early date. By a novel arrangement of the leading-in wires and new designs of testing apparatus faults can be readily localised. The new Exchange is to be lighted througout by electricity, about 100 incandescents being required. The heating arrangements are of the simplest and most effective kind, and have been tested with satisfactory results. In addition to the new Lime-street building, an Exchange is to be erected at Holborn, ultimately intended to replace the Chancery-lane and Smithfield Exchanges, and thus further consolidate the Company's metropolitan system. It is anticipated by the Company that the new arrangements, combined with the complete substitution of the metallic-circuit system, will immensely improve the Metropolitan telephone service, at an estimated ultimate outlay of between £100,000 and £150,000.

Woodhouse and Rawson United (Limited).—The creditors and shareholders in this Company, which is now under receivership, have this week received several circulars giving some particulars regarding the position of affairs to date. No. 1 is a circular of the Committee of Inspection; No. 2 a letter from Mr. F. D. Leslie, receiver for the debenture holders; No. 3 a circular from the Epstein Company; No. 4 is described as a "Memorandum of Facts" in connection with the Epstein Company; Nos. 5 and 6 are termed "Testimonials" and "Experts' Reports;" and No. 7 is a form of application, in which the shareholders and creditors of Woodhouse and Rawson United (Limited) are invited to take up £12,000 in Seven per Cent. Mortgage Debenture Stock of the Epstein Electric Accumulator Company (Limited). It would appear that part of the assets in the Woodhouse and Rawson failure consists of a considerable interest in the Epstein Company, which would, it is urged, be considerably increased in value if the sum of £12,000, or thereabouts, can be raised as additional working capital for the Epstein Company. Mr. Leslie, the Receiver and Manager for the debenture holders in Woodhouse and Rawson, applied in January last to sell the Epstein assets, but the trustees for the debenture holders and others strongly opposed the sale, on the ground that the price was inadequate, and the Court refused its consent. The Committee of Inspection appointed at the meetings of creditors and shareholders held in December last are satisfied that the Epstein accumulator is a "serviceable article," and that the proposal to apply a portion of the holding of Woodhouse and Rawson in the Epstein Company to a scheme by which additional working capital will be obtained for the latter is worth the consideration of the creditors and shareholders in the former. In order to increase the value of the Epstein shares, Mr. Leslie has applied to, and obtained permission from, the Court to cancel a contingent debt of £11,000, a portion of the asset referred to, and to offer to those who may apply for the Second Mortgage Debenture Stock now offered a bonus of one fully paid Ordinary share of £1 in the Epstein Company for every £2 of Debenture stock applied for, the balance of 28,150 Ordinary shares and 511 Vendors' shares remaining in Mr. Leslie's hands, awaiting "the expected development of the Epstein Company." Circular No. 3 states that (subject to confirmation) the Directors of the Epstein Company have completed negotiations for the working of the United States and Canadian patents. This communication is dated April 23rd, and the confirmation has to be made within six weeks from that date. Should this arrangement be satisfactorily negotiated, the Epstein Company is to reap a considerable benefit. The application, for this Debenture stock must be sent in by Saturday, the 5th inst. The various circulars bear different dates, commencing with April 10th, and ending with April 23rd. Many of the creditors did not receive the circulars until May 2nd, the original date for the sending in of applications.

A New Cigar Lighter.—In an electrically lighted house matches are comparatively rare, as the smoker finds to his annoyance, and there is a real need for some electrical kindler. An attempt has been made by the General Electric Company to provide something better than the rather clumsy platinum wire in series with a 32-c.p. lamp. In the new device a 32-c.p. lamp is used, but the contact is so brief that the lamp is scarcely rendered hot, and that only for an instant, probably having no effect on the meter. One terminal of the lighter is connected to the lamp and this is connected to a corrugated carbon block, set on a china reservoir containing methylated spirit. A wire covered with asbestos is kept in this reservoir and is attached by a flexible cord to the other terminal. The wire is struck against the carbon block, the circuit is rapidly made and broken, and the spirits are ignited by the sparks. A 16-c.p. lamp on 100 volts is hardly sufficient. In its present form, the device, which will serve for pipes as well as for cigars, is far from ornamental, and needs refilling with spirit from time to time.

"Advertisers' A.B.C."—Mr. T. B. Browne, of Queen Victoria-street, E.C., and Buchanan-street, Glasgow, announces the issue of his well-known "Advertisers' A.B.C. and Advertisement Press Directory" for 1894. In addition to a revised and enlarged list of newspapers and official statements as to their circulation, &c., the book has a Provincial Newspaper Gazetteer containing more than 2,400 towns and places in the United Kingdom with the newspapers published and circulating therein. The price of the book is 10s. 6d., and it can be obtained of all booksellers.

Shipping.—The publishers of the *Handy Shipping Guide*, a weekly periodical well known in shipping quarters, celebrate the seventh year of the *Guide's* existence by the publication of a Supplement, which is to be continued monthly, dealing with matters of interest to the shipping world.

Alleged Libel.—In the action brought by Augustus Fleet, solicitor, of Hatton-garden, London, against the proprietors of the *Pall Mall Gazette*, in connection with the electropathic belt business, the *Pall Mall Gazette* has proved victorious; and Mr. Justice Wright, who tried the case, said he agreed that newspapers had to perform important public functions, and it was impossible for them to do so if the law considered they were under penalty to keep mention of every incidental name out of their remarks. The jury returned a verdict in favour of the *Pall Mall*, and judgment was given accordingly.

Belfast.—The Board of Guardians have been staggered by the amount of the gas bill for the past year, which shows a considerable increase, and have appointed a committee to inquire into the question of lighting generally, and, in particular, as to the cost of an electric lighting installation for the buildings. An expert is to be called in to advise the committee.

Birmingham.—In reference to the Birmingham Electric Light and Power Order (1894), which is being promoted by the Birmingham Electric Supply Company (Limited), the General Purposes Committee of the Corporation have reported that the Draft Order did not appear to them to give sufficient advantages to the public in return for the important concessions sought by the Company, and an objection was therefore lodged, on behalf of the Corporation, with the Board of Trade. This led to negotiations between the parties, and it was ultimately agreed that the price for electric current should be reduced from 10d. to 8d. per unit, and the minimum charge per quarter from £3. 10s. to £3. 6s. 8d., these reductions to apply to current supplied under the existing orders as well as under the new Order. The promoters are to lay mains in all the extended area within two years from the confirmation of the Order, and the clauses of the Board of Trade Model Order with respect to street boxes, supply of current to owners and occupiers and public lamps, &c., are to be inserted. The promoters of the Order have agreed to these condi-

Digitized by Google

tions, and the Committee have given the necessary consent to the application.

Bradford.—The Corporation have appointed a deputation to visit Halifax to inspect the electric lighting works there in connection with the refuse destructor.

Bristol.—A Local Government Board inquiry has been held here by Col. Ducat, R.E., to consider an application by the Town Council for sanction to borrow £24,650 for electric lighting purposes. £9,468 represents additional expenditure over and above the original estimate, and it is proposed to expend £15,181 on new works and extensions. It was pointed out by Mr. Preece that the additional expenditure was not due to any error in the original estimate, but to extraordinary difficulties that had occurred in erecting the lighting station buildings. It was his opinion that Bristol has now the best central electric lighting station in the kingdom, so far as the structure is concerned.——The Corporation contemplate extending the electric lighting mains to Clifton and Tyndall's Park for private supply, in addition to other extensions which have been agreed to.

Chelmsford.—There has been some difference of opinion between Messrs. Crompton and Co. and the Town Council as to the purchasing clause in the Provisional Order. The Council endeavoured to insert a clause to the effect that the purchase should be limited to such parts of Messrs. Crompton's undertaking as were used solely for the public and private lighting of the borough, but the Board of Trade declined to agree to this, and, instead, have inserted a clause under which it is stipulated that Messrs. Crompton and Co. shall sell the undertaking authorised by the Provisional Order, with all lands, buildings, materials, and plant used in connection therewith. It was pointed out by the Board of Trade that similar contentions had arisen at Liverpool and Reading, and had, in each case, been settled by the insertion of a clause similar to the above. It was ultimately agreed to leave the final settlement of the matter in the hands of the Board of Trade.

Church Lighting.—Redcliffe Church, Bedminster, is to be lighted throughout by electricity.

City of London.—At the last meeting of the Commission of Sewers, Mr. Ross reporting on the number and cost of the gas lamps displaced by the arc lamps in the main thoroughfares, said that the 479 arc lamps cost £12,454 per annum, whereas the 1,315 displaced gas lamps cost, for lighting and maintenance, £4,631. Mr. McCarthy commented upon the increase, and asked whether the Commission intended to light the side streets by electricity, which he said would cost another £10,000 per year. Mr. Burmester replied that the Streets Committee was considering that point.

Country House Lighting.—Messrs. Drake and Gorham are lighting the Devonshire mansion of Mr. T. B. Bolitho, M.P., with about 120 incandescents. A petroleum engine is to be used, driving an E.C.C. dynamo, to provide current for a battery of 53 D.P. cells.

Darlaston.—The Local Board have decided to consult an electrical engineer, with a view of ascertaining the probable expense of obtaining a Provisional Order.

Derby.—The Local Government Board have sanctioned the borrowing of £5,000 for extensions to the electric lighting of this town, repayable in 20 years. It is intended to supply the light to the two Police Stations and the Market Hall.

Destructive Fire at the Royal Electric Company's Works in Montreal.—While the Earl of Aberdeen was reviewing the fire brigade in the Champ de Mars at Montreal, on Tuesday afternoon, a destructive fire broke out in the Royal Electric Company's Works. Owing to the firemen being in full dress for the parade some delay occurred before they set to work to subdue the flames. Twenty-five dynamos were destroyed, and when the fire was at its height the fly-wheel of the works engine burst, the heavy fragments crashing into the surrounding buildings. There was no loss of life, but many remarkable escapes are reported. The loss of property is estimated at over $100,000.

Dover.—The Dover *Standard* is of opinion that "as a lighting agent there is no doubt that electricity exceeds all others," and "that it is not a heating agent, and as such can never enter into competition with gas." Altogether the views of the Dover *Standard* on electric lighting *versus* gas show a considerable acquaintance with the subject.

Dundee.—On Monday last a deputation, consisting of the whole of the Dundee Council, visited Coatbridge "in the interest of the proposed introduction of the electric light into Dundee."

Edinburgh.—The Lighting Committee of the Town Council have instructed their consulting and resident engineers to prepare and submit a report as to the annual and capital cost of the extension of the electric light to George-street, St. Andrew's-square, Charlotte-square, and the thoroughfares leading from Prince's-street.

Electric Organs.—A new organ with four manuals and pedals, 74 stops, and 3,600 pipes has been erected in the parish church at Ormskirk, near Liverpool, and has been fitted with the Hope-Jones electric appliances.

Electro-Medical Quacks.—These gentlemen are having a bad time all round. It appears that at Nelson, New Zealand, a Prof. Richard, who is described as a medical electrician, is in trouble, and has made tracks to avoid the resentment of the populace.

Electro-Harmonic Society.—The report just issued shows that 35 members have been elected during the past season, against four lost by death, 20 resignations, and 21 struck off the register. The total number of members is 328. The annual general meeting is to be held on Wednesday next at 4.30 p.m., at 28, Victoria-street, S.W. The balance-sheet shows, subject to audit, a surplus balance in hand of £104. 10s. 5d.

Fareham.—A public meeting of the ratepayers was held in the Foresters' Hall, on Thursday last week, to consider the question of entertaining an offer of the Fareham Electric Lighting Company (Limited) to sell their business and undertaking to the Local Board. Mr. J. Blake, the managing director of the Company, spoke at considerable length in favour of the proposed purchase by the Local Board, estimating that the cost of taking over the Company's plant, purchasing duplicate engines, and laying down one mile of mains underground would be £8,000, and calculated that the concern would pay its way after the first year or two. An amendment was proposed to the effect that the Local Board abandon their offer to purchase the plant, several balance-sheets issued by the Company being very severely criticised. On the question being put, the Chairman declared the amendment carried, but Mr. Blake demanded a poll.

Hampstead.—The Electric Lighting Committee of the Vestry have selected Wednesday, the 23rd inst., as the date for laying the foundation stone at the electric supply station.

Huddersfield.—The first annual statement of the Electric Lighting Department of the Corporation shows a deficiency of £2,547 on the revenue account.

Ipswich.—As previously stated, the Town Council have decided to take the necessary steps to obtain a Provisional Order. Mr. Pratt, a member of the Council, in moving the adoption of a motion to this effect, elucidated a carefully prepared scheme for the lighting of the town. He pointed out that in many places the electric light had been introduced, and was not only paying its way, but was realising a fair profit. He advised the selection of the site of the old Vulcan Brewery for the central station, and estimated the sum required for establishing the works at £10,000. After a very lengthy discussion, the motion to take immediate steps in the matter was carried.

London County Council.—At Tuesday's meeting Col. Ford presented a petition from the ratepayers of North Lambeth, calling attention to the Act of Parliament last session providing for the lighting of Waterloo Bridge by electricity, and praying that the Council will no longer delay carrying out the work. The petition was referred to the Highways Committee.

Lynton.—Mr. Benn has transferred his electric lighting works to a company, who propose to obtain greater water power, and by this means make the light more efficient. The Local Board have promised that, upon being satisfied that the additional works are competent to give the better light promised, they will be prepared to extend the lighting contract to the new company for 14 years.

Manchester.—The Gas Committee have presented their report, which announces that owing to the great support accorded the electric light, it has been found necessary to considerably increase the plant.

Mill Lighting.—Messrs. Bennett and Druce have been instructed by Messrs. Tootal, Broadhurst, Lee and Co. (Limited) to re-arrange the electric lighting installation at their extensive mills at Bolton, and to considerably extend the same.

Oswestry.—At the last meeting of the Town Council it was decided to purchase the Provisional Order obtained by the Oswestry Electric Light and Power Company (Limited), for the sum of £350.

Poplar.—The District Board of Works on Tuesday discussed the report by Mr. W. H. Preece on the advisability of adopting the electric light for the district, which we abstracted in our last week's issue. The Board on the whole favourably received the report, and referred it to the Works Committee for consideration.

Portsea Island (Hants).—The Board of Guardians have decided to invite tenders for lighting the Municipal offices by electricity.

South Shields.—At the meeting of the Town Council on Wednesday, a report and estimate prepared by Mr. Joseph A. Jeckell, the Borough Electrical Engineer, was discussed and adopted, and permission granted to apply to the Local Government Board for sanction to borrow £22,000 in accordance with the estimate. A deputation was also appointed to visit several central stations recently erected.

Digitized by Google

STIRLING.—The Town Council have received further communications from the Scottish House-to-House Company in reference to the application by that Company for a Provisional Order to light the Stirling district. A letter has also been received from the representatives of the Caledonian Electric Supply Company, in which, after referring to the decision of the Board of Trade in the matter of the Company's Provisional Order, the writer asks whether the Council would be prepared to enter into an arrangement for a joint application by the Company and the Council. As the Council have decided to themselves apply for a Provisional Order, it was agreed to acknowledge the receipt of the letters, and to take no further steps for the present.

THETFORD.—The Town Council, on Tuesday, decided to light St. Peter's clock by electricity at an estimated cost of £8 per year for 16-c.p. lamps.

TOXTETH.—The Board of Guardians are considering the advisability of lighting the workhouse by electricity. It is proposed to employ the 12-H.P. steam engine now at work for laundry purposes during the day to work the electric light installation at night.

WEST HARTLEPOOL.—The Town Council have received an offer from the Electric Construction Company to light the town by electricity. This Company have the contract for running the electric trams in the Hartlepools, and point out to the Council that, as the trams will be run by electricity, the town can be lighted by the same agency at a greatly reduced cost. The Council have decided to obtain further information, and will consider the matter at an early meeting.

WESTON-SUPER-MARE.—It is stated that, in response to the circulars issued by the Local Board inviting support to the electric lighting scheme, No. 1 District, which includes several of the principal business premises, has applied for about 1,000 incandescents; and that, if the Board receives similar support from the other districts, immediate steps will be taken to carry out the Provisional Order.

WINDSOR.—A petition is being signed urging the Town Council to take immediate steps to provide the town with electric light.

WOLVERHAMPTON.—The Corporation have decided to lay the foundation stone of the new electric supply works in the Commercial-road on the 21st inst.

WORTHING.—The Town Clerk has been instructed by the Town Council to make inquiries from the various towns using the electric light for particulars as to cost, &c.

COMPANIES' MEETINGS AND REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The forty-first ordinary general meeting of this Company was held on Wednesday at Winchester House, Sir John Pender, G.C.M.G., M.P. (Chairman), presiding.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting and the minutes of the previous meeting.

The CHAIRMAN: I will go over in detail some of the points in the report, so that you may have a better knowledge of what we have been doing during the last six months. The receipts for the half-year ended December 31, 1893, were £96,262, against £106,860 in the previous half-year showing a decrease of £10,598. As compared with the income of the corresponding period of 1892, when the receipts were £113,892, the past half-year showed a falling-off of £17,630. The receipts from messages exhibited a decrease of £10,654, while the miscellaneous receipts from interest, rents, and transfer fees, give an increase of £56, resulting in a net decrease, as before stated, of £10,598. The average value of the Brazilian milreis was in the half-years ended December 31, 1893, 10 1/16d.; June 30, 1893, 12¼d.; and December 31, 1892, 13⅝d. This further fall in the exchange value of the Brazilian currency collected accounts, in a large measure, for the decreased receipts from messages. It is to be remembered that on April 1, 1893, a reduction was made in our tariffs, and therefore the first three months of 1893 had the advantage of higher tariffs than those existing at present. The expenditure for the half-year was £24,284, and for the previous half-year £40,580, showing a decrease of £16,296. There is a decrease in cable repairs of £14,607, in working expenses at stations of £1,960—together £16,567; and an increase in London expenses £147, and in other items of expenditure £124, making together £271—or a net decrease of £16,296. The general expenses in London were £2,761, an increase of £147 compared with those of last half-year; but, compared with the corresponding half-year, when they were £2,756, the figures are practically the same, there being a difference of only £5. The working expenses at stations showed a decrease of £1,960, the net result of increases and decreases under many heads, the principal decreases being—salaries of staff £431, agencies £1,068, and electrical expenses and maintenance of land lines £853. There is very little this half-year for a Chairman to put into a speech, but in addition to any special matter, the following subjects will admit of comment. First of all the accounts. These are not the final accounts for the financial year. The usual interim dividends at the rate of 6 per cent. per annum has been paid, and £20,000 has been transferred to reserve. Last half-year we were only able to transfer £7,000, but for the five years previous to 1893 the average amount so transferred half-yearly was £43,500. On December 31st last the reserve fund stood at £668,000, a very satisfactory sum indeed. It is absolutely necessary to provide these large accumulations in order to be able to supply new cables when required. With all our experience up to the present time we cannot tell what the life of a cable really is. We know that if a cable is laid on safe ground that it lasts for a very long time; and, on the other hand, if it is laid in a rocky ground, or anywhere where it is suspended, or where there is friction, we know its life is thereby very much diminished. But the principle upon which we proceed is to go on repairing and renewing and putting in new pieces of cable where necessary each half-year. It is part of our business to keep up our system in as efficient a condition as possible, and that efficiency was maintained to a very great extent by the repairs and the new cable put in when the repairs are effected. There are two cables to be maintained and eventually renewed, and that fact accounts for the large amount we deem it necessary to place to reserve. As you are aware, one of these cables is 20 years old, and therefore it is, at all events, approaching a period of age which causes us to be careful in providing for its renewal. Gentlemen, as you can all detect, I am suffering from a sore throat, and it begins to trouble me just now, when I want my voice, and so I shall be obliged to cut my remarks short on that account. But there are one or two points I think I must refer to. One of these is that the exclusive privilege granted by our concession expires in December with the Brazilian Government. We have had special privileges during the last 20 years, and we are anxious to retain as far as possible those privileges for another 20 years. We are sending out an agent to negotiate with the Government of Brazil, and we are hopeful that if they take the same reasonable view that Governments generally take in dealing with submarine telegraph companies that we shall arrive at a satisfactory arrangement with them, and one which will assure our connection with the Brazilian Government. The Brazilian Government] are undergoing a change, and we hope that when the civil war, now practically terminated, is at an end, that a sound Government will be established, and that with its establishment prosperity will return to their territory. In the returning prosperity we, of course, shall more or less participate. It will be a great satisfaction to us to see the political position of Brazil strengthened, and to know that the Government are disposed to deal with us in a fair and reasonable manner. Judging from our experience of how these things have been dealt with by other Governments, we cherish the hope that the Brazilian Government will treat us with the same liberality that we have received elsewhere. We have secured an interest in a concession obtained by our partners the Western and Brazilian Telegraph Company for the purpose of laying an additional cable between Brazil and Argentina when required. In the event of competition with the American Company which is endeavouring to take as much of the traffic as they can from us, we think it will enable us to meet that competition in a satisfactory way. Of course, we have had to pay for that concession. No concession of the kind is obtained anywhere without payment, but we consider the payment we have made for it is only a fair one, bearing in mind the very great advantages which we shall derive from having the control of that part of the coast. If we had not got it it might have been obtained by what is called the Central and South American system, and then the messages would have been carried by the Galveston route. We have, however, secured the option of laying that cable, but we shall only lay it if we find it is necessary in our interests to do so. If I had my voice at command I would go into further matters, but I think I have given you the outline and heads of our operations during the past half-year. The current half-year will be one of some considerable interest, because, as I have said, our agent is going out to Brazil on important business for us. I hope he will find things proceed pleasantly and satisfactorily; and when, in six months time, I again address you, I may be able to tell you that we have got a new lease, which will be advantageous, not only to the telegraph public generally, but of special advantage to the shareholders of this Company. I beg now to move:—

"*That the report of the Directors and accounts to December 31, 1893, now submitted, be approved and adopted.*"

The Hon. W. ST. JOHN BRODRICK, M.P., seconded the resolution.

Dr. TREWHELLA asked for some information as to the new land lines between Buenos Ayres and Valparaiso. Speaking as an individual shareholder, he thought the Board had shown considerable prudence in securing the option to lay a cable between Rio and Buenos Ayres.

The CHAIRMAN: After delay from unexpected causes the lines of the Pacific and European Telegraph Company between Buenos Ayres and Valparaiso were opened in March last with promising results. We are now enabled, in connection with the West Coast of America Telegraph Company, to deal with traffic to and from Chili, Peru, and Bolivia. In doing this we are competing with what you know as the Galveston route, which, in like manner, competes with us at Buenos Ayres for the East Coast traffic, particularly that of Argentina, and in a lesser degree that of Uruguay. It is our wish to conduct this competition in a friendly spirit and in an honourable and fair manner. The opening of that line is, so far as we can judge, satisfactory. It must be very satisfactory indeed in the future. While this competition is going on we have been under the disadvantage of our opponents having had possession of the ground for about two years, while our cable was being constructed. But we have the hearty co-operation of the Chilian and Argentine Governments in the work we are doing, and I am satisfied with our prospects. I hope I may live to see one system existing, so that communication with Chili and Peru will be upon as sound and good a basis as that of any submarine telegraph company in the world. At the present time we are having competition. There is a company called the South American Company, which has come into Pernambuco at reduced rates. We think we are strong enough to meet any such competition, and at all events we will make it rather

hot work for anyone who attempts to oppose us in that way. We do not presume upon our wealth, but we presume upon our strength, and I think our strength as pioneers of the system is such that we are entitled to support from the Brazilian Government, and we think that with anything like a moderate support from them we shall be able to control to some extent the telegraph system existing to Brazil. We do not want to be arbitrary; we do not want to say or do anything to companies that may think they can compete with us. All I ask them to do is to compete in fair and honourable ways, not to do it by cutting, but by good service, and those who do the service the best are entitled to gain the reward. I hope those who are opposed to us will take the same view, and if they do we shall get on fairly well together.

The resolution was then carried unanimously.

Dr. TREWHELLA, in proposing a vote of thanks to the Chairman and his co-Directors, said he happened to be associated with a great many companies, but he did not recollect one Board in which the shareholders could repose greater confidence in their administrators than in the Board of the Brazilian Submarine Telegraph Company.

Mr. P. A. COARD seconded the proposition, which was agreed to.

The CHAIRMAN, in acknowledging the compliment, said: On behalf of my colleagues and myself I most sincerely thank you. We have only one object in view, and that is to make our Company a successful one, and our hands are strengthened when we have proof of your confidence and co-operation. It is our desire that the shareholders should know as much as is consistent with the interests of the Company, and when I tell you we have nothing whatever to hide, and there is nothing I do not desire you to know, you may be sure we are going on in a very clear and safe way.

The proceedings then terminated.

Phonopore Company (Limited).

The fifth annual general meeting of this Company was held at Winchester House, London, E.C., on Monday last. Mr. Henry Seebohm (the Chairman of the Company) presided.

Mr. CHARLES ISAAC (the Secretary) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN, in moving the adoption of the report and the balance-sheet, said that the late Board, when it took over the management of the Company from the previous Board, did so with a light heart. They thought that all the difficulties had been overcome. They thought they were in an ideal position upon which to build up a prosperous future. They thought they had a large stock of excellent instruments ready for commerce, and ample capital. Members of the late Board, and electrical experts that they consulted, especially Mr. Spagnoletti, took a very sanguine view of its position. They could, therefore, well imagine that in the face of such strong evidence in favour of its perfection it took them a very long time before they were absolutely convinced, as they were now, that what they possessed was little more than a pretty electrical toy. There were great difficulties to be overcome in the practical working of it. They were then, no doubt, in an ideal position, and not in a practical one, and those difficulties were continually developing from day to day, and from week to week correspondence was laid before the Board in one almost uniform result. Everyone was anxious to use the instrument, and everyone when they had tried it were very much pleased with it, but by-and-by they found that the adjustment of it was so delicate that it was more than the average telegraph clerk was capable of grappling with, and the Board had constantly to send out messengers to put instruments right which had somehow gone wrong. There was another obstacle to the success of the instruments owing to the induced currents interfering with the wires, the telephone wires especially, and the Board were obliged, after a year's working, to come to the conclusion that one of two things would have to be done—either to improve the system itself, or else to wind up the Company and throw the whole thing overboard as a failure. It was extremely disappointing to the Board, and as the shareholders might imagine extremely disappointing to the late Chairman of the Company. He (the late Chairman) was absolutely convinced, as all members of the Board were, that the gentlemen who reported on the future of the Phonopore had taken far too sanguine a view of its capabilities, and he naturally felt great disappointment, especially at his age and at his time of life and position, so that he was at last compelled to give in and resign his seat upon the Board. The statements which had been made with regard to the instrument had not been borne out by the results. He had no doubt that all such statements had been made in an absolutely *bonâ fide* manner and in all good faith. He believed that Mr. Langdon-Davies believed every word he uttered, although those statements had not been borne out by facts. He held that it was simply a matter of opinion, and he did not accuse in any way those who made those statements of saying anything which was not true; but there were certain points which were altogether incorrect, and which results had since proved to be so. For instance, that gentleman represented that in the year 1889 the position of the Company was, upon the whole, so satisfactory that there was sufficient profit to pay the whole of the expenditure and to carry forward £266 to the next year. That might have been true, but what he wished to call the attention of the shareholders to was the fact that that profit and more was entirely derived, not from receipts derived from the Phonopore, but from the issue of shares at a premium; and in that year in which the Company was represented to have made £266 profit they absolutely made a loss of £4,721, which was almost precisely the same figure as in 1891. In 1890 the loss was £1,000. In that year the loss was not so great because the Company had not so much money, and they were unable to spend more. In the following years there was but little variation, the loss then amounted to £200, and that loss was owing to the fact that the Company had been carrying on experiments, and had been trying to get the instrument more perfect. He was pleased to say that they had to a very great extent succeeded in doing so. The Board now found that when they sent out instruments they were followed by more orders, and that in itself was a satisfactory matter. People were now taking the instrument, and were grumbling, not at the imperfections of the instrument, but at the price. Most of the railway companies had been hard hit during the past year, and had lost a deal of money owing to the coal strike and other matters, in consequence of which their great desire had been to work upon an extremely economical basis, and therefore did not wish to spend a farthing more than they could possibly help. The Directors hoped that in the future the sales of the instruments would continue to increase, and as they had now constant inquiries being made both at home and abroad, he thought they might look forward to such taking place. The Company had sent out people to instal fresh instruments, and the results of those instruments had been much more satisfactory than they were twelve months ago. The Company had made several important improvements, but they regretted that at the present time they saw no immediate prospects of satisfactory profits. Amongst the improvements which had been made to the instrument were a new receiver and a new Phonopore sounder, and they were now able to work the instrument upon a single needle key, as well as upon the Morse system. Those who were capable of going minutely into the technical part of the matter would see that the Board had placed at the end of the report a circular signed by Mr. S. P. Thompson, which he (the speaker) considered showed that the position of the Company in that respect was ideal. The Directors had tested the instrument, and were now of the opinion that they had got an instrument which would meet the requirements of the market, and they hoped that with that instrument, as alluded to in the circular, the position of the Company would in the future be much better than it was at present. There was one matter to which he wished to allude with regard to the old Phonopore, or, to speak more correctly, the old patents of the Company, which proved a failure with respect to its results, and that was the rate-governor. The old Board bought that patent from Mr. Langdon-Davies for something like £10,000, and they now found there was not one of the instruments which possessed that rate-governor. What they had been able to find was not used as a governor at all, but only as a break: it did not, therefore, need any patent at all, and had been throughout a complete failure. It seemed to him that the old Board had bought a pig in a poke; the arrangement was made upon the specifications of the patent, and so completed. It was difficult to conceive how such a proposal could have been brought forward, and whether they looked at the sublime audacity of the seller, or the credulity of the buyer, it was impossible to understand how such a transaction could have taken place. It was, however, of course, very easy to be wise after the event. When Mr. Langdon-Davies sold the instrument he, no doubt, thought that he was selling an instrument of enormous value, and there was no doubt that the Board were of the same opinion when they purchased it, although it had subsequently turned out to be a failure. The statements which he (the speaker) made on that occasion were made on the authority of those who knew a great deal more about electricity than he did, and he believed that they were all absolutely true. Although the prospects of the Company were much better than they had been lately, yet the shareholders must not fancy that they were going to win in a canter; they had still got a tremendous fence before them, and it was possible that they might come a cropper before they got through. The difficulty which they had to face was that there was no reasonable prospect that the money in hand would hold out until the receipts balanced the expenses. There could be no doubt whatever that in order to keep the Company in a proper position, fresh capital would have to be raised in some form or the other. That would have to be done without doubt before the Company was really on its legs. The shareholders might rest assured that the prospects held out to them some years ago were absolutely pure unmitigated moonshine. He was extremely sorry he could not lay before the shareholders a better report, but he had to the best of his knowledge and belief laid before them the position of the Company. He did not wish, on looking back upon the difficulties through which the Company had passed, and the extremely sanguine views which had been expressed by Mr. C. E. Spagnoletti and others, to exaggerate things at all; and before he moved the adoption of the report he felt it his duty to draw the attention of the shareholders to the fact that, although Mr. Spagnoletti had at one time expressed extremely sanguine views, yet for the present position of the Company they were all indebted to his exertions and to those of his staff, and he hoped that those exertions would not be without fruit if the Company could get through its difficulties. The Chairman concluded by moving the adoption of the report.

Mr. W. HART seconded the motion.

Mr. LANGDON-DAVIES said he rose with regret to move an amendment as last year. On the last occasion he moved a resolution in language of the greatest possible reserve, because he was not so sure of matters as he was to-day. He knew more now than he did then. The effect of that resolution was to suggest that unless the management had radical reforms introduced into it they would soon find themselves in the position described in the first paragraph of the report as follows:—"The explanation is that practical experience unfortunately proved that the instruments required considerable modification to make them marketable, and it was necessary to alter them in nearly every detail; but from the successful working of those which have been recently disposed of, the Board feels satisfied that this, after great delay and cost, has been at length accomplished." That was what the present Board offered to the shareholders as an explanation of the disastrous losses they had suffered. To decide whether or not that was a genuine explanation he had decided to devote his attention. He did not object to Mr. Seebohm as Chairman, and there was no one he would care to replace him with; but he wished to know what technical knowledge that gentleman possessed. As to Mr. Spagnoletti, he desired to make his remarks temperate and inoffensive, but he thought it behoved them to consider whether the position occupied by

Digitized by Google

that gentleman as Managing Director in that Company was the right one to be occupied by him. Mr. Spagnoletti had been at work upon improving the Company's instruments. It was stated that that gentleman had been for 37 years the chief of the telegraphic department of the Great Western Railway Company, and for one year the President of the Society of Telegraph-Engineers. He hoped that he had a due regard to the importance of both those positions, but he asked whether that justified him to occupy the position he did in regard to the latest, or one of the very latest, inventions in electrical telegraphy; for the Phonopore involved a new principle of action. He (the speaker) had surrounded it by instruments and parts that obeyed natural law, and it was not understood 37 years ago. He maintained that Mr. Spagnoletti, who had honourably fulfilled his duties to the Great Western Railway Company, had not, he (the speaker) thought, himself advanced with the progress of electrical science. He said that they were informed on former occasions that Mr. Spagnoletti was a man who could sell their instruments.

A SHAREHOLDER: Who said that?

Mr. LANGDON-DAVIES: Sir Mountstuart Grant-Duff said so in perfect good faith. Continuing, he remarked that a test of the original instruments was made on the Great Western Railway between London and Bristol. The test was for about six months, and the instruments were used under the supervision of Mr. Spagnoletti, who approved them upon behalf of the Great Western Railway, wrote to the brokers of this Company in favour of them, and accepted a position for three years to sell them. Two more sets were asked for and fixed for the Great Western Railway. He did not think that this bore out the statement of the report that the instruments were not marketable. Investigations had been made in the laboratory and on the line reports made upon them. He would mention one or two experts who had spoken in favour of them, viz., Lord Kelvin, Sir Frederick Bramwell, Sir A. Clark, and Dr. S. P. Thompson. There were reports from Spain, Paris, and Frankfort, where the Phonopore had stood fire. Mr. Spagnoletti had said that these instruments would not work 500 miles, and he agreed that that was so. He was distinctly told not to make instruments beyond 200 miles. It was not worth while representing that 500 miles was necessary, because it could be done—it was only a question of money. 200 miles was the most common circuit, and the one that would pay them best to make Phonopores for. He would be pleased for a committee of investigation upon his instruments and his work. He challenged them to appoint such a committee. As to his circular, he did not stand alone. He was the representative of forty shareholders, who had studied the matter individually, and had come to the one conclusion he had laid before them that day; forty minds had considered the matter, and they were entitled to consideration. He had plenty of information in regard to finance which he preferred to tell to a committee than to the meeting. He had 6,800 shares, representing the whole of the reward that he received for his invention. He was offered £30,000 cash for those shares, which he refused, giving as his reason that he had determined to stand by the general body of shareholders, and share equally in profits with them. He had stood to that resolution, and he intended to stand by it. He might devote himself to more profitable work, but he wanted to stick by the Company, and help the shareholders to get what they ought. They had elements on that Board that would help that end, and of others that would oppose it. He begged to move the following amendment:—

"*That the consideration of the report and accounts for the year 1893 be deferred to an adjourned meeting to be held within a month, and that a committee of shareholders be appointed to join the Board in considering the report and general condition of the Company's affairs; the Directors and the committee to make a joint report or separate reports as they think fit.*"

What they wanted to do was to reduce the Board to three, to pay that three their fees, and to abolish the office of Managing Director, appointing a business manager in his place.

Mr. PILBURY seconded the amendment, and said, if the instrument was only "a pretty electrical toy," the Board was a farce to remain in office, and to spend money in perfecting it. He had heard Lord Kelvin say, on the other hand, that he was surprised that the instrument which had so much in it had not become better known. He urged the shareholders to see that they got a good return eventually for their money.

Prof. S. THOMPSON said that he had gone out of his way on many occasions to further the interests of the Phonopore. There was the germ, and more than the germ, of a great invention in it. Referring to the old instruments that were sent to Frankfort in 1891 to the electrical exhibition, he gave an address there on the Phonopore, and they had the instrument working from Frankfort to Homburg. The instrument was tried on the right and left banks of the Rhine, and in all cases these instruments had come back upon their hands as requiring too much adjustment. He thought they owed a great debt to Mr. Spagnoletti. As to the rate-governor, he was very much surprised that they acquired it at such a heavy expense, and it would be a surprise to everyone who knew the circumstances from first to last.

Mr. LANGDON-DAVIES said that he thought they had better have a practical business manager who understood telegraphy from a practical point of view, rather than a man who had only been head of a department and seen others work.

Mr. KESKY said that the amendment was equal to a vote of want of confidence in the Board. He would like to know the stake that the Board had in the Company. He (the speaker) thought they would be unwise to pass the amendment upon anonymous information, and to censure the Board thereby.

The CHAIRMAN said the holding of the Board in shares was about one-fourth of the capital of the Company.

Mr. SPAGNOLETTI expressed regret that the discussion had drifted into such uncomfortable matters. He much regretted that they had had such universal complaints as to the old instruments. Complaints came even from the Great Western Railway, and alterations had to be made. From the Midland complaints came from the company, both as to the instruments and that the management had not fulfilled its promises. In every case the complaint was the same. This was last spring. They tried to push the trade abroad—in Vienna, Holland, Germany, and France. Every one had been sent back. There was not a single working installation on the Continent, except one in Bulgaria, which was unsatisfactory. As to France, they were shown at the Exhibition in 1889, but they were all rejected. Since then they had tried the new instruments in Paris, on the Western Railway, between Paris and Rouen, and they had given great satisfaction. They were in hopes of orders at an early date. The instruments were being tried on the State line, the Northern, the Western, the Eastern, the Orleans, and the Paris, Lyons and Mediterranean Railways. The Company would not have to canvass in France, for the Crédit Lyonnais had asked for the agency, and the Prefecture of Police were considering it. In Germany they declined to have anything to do with the thing, and had sent them all back. They had had a letter from the Great Southern and Western of Ireland Railway Company, who declined to give the instrument a trial, because the clerks could not use the key instead of the needle. The Company had now made an instrument which would do as well as the needle. They had ordered 18 trial instruments to be made. The railway companies said that this Company was charging far too high, but he did not think that that was so. As to the rate-governor, they had not got such a thing at work on the whole system. He said that what Mr. Davies claimed as the essential part of his invention in the rate-governor did not exist upon any of their instruments at all. He regretted to be so emphatic, but it was the fact. The plain position was that the instruments would not do that work; they interfered with the telephones too much; complaints came from everyone. The new instruments on the North British were doing well, and the account for them had been paid. The North-Western engineer did not like the instruments, but had been worried into a promise to try them. The regulation had been altered and improved, and the instruments could be put in without adjustment; relays were essential to the instrument.

Mr. LANGDON-DAVIES: Nonsense?

Mr. SPAGNOLETTI: If you take it out of the Phonopore as it now is, it is like taking the mainspring out of a watch.

Mr. KIMBER supported the amendment.

Mr. MOCATTA urged the shareholders to support the present management.

The amendment was put and lost by 11 votes to 25, including the Directors.

The report and accounts were then put and carried by 18 votes (exclusive of the Board) against 10.

The retiring Directors and auditors were re-elected.

The proceedings (which had lasted upwards of two hours) then terminated.

Submarine Cables Trust.

The twenty-third ordinary annual meeting of the certificate holders in this Trust was held yesterday at the offices, Winchester House, Old Broad-street, London, E.C., under the presidency of the Marquis of Tweeddale.

The SECRETARY (Mr. A. Brodrick) read the notice calling the meeting and the minutes of the last meeting, which were approved by the present meeting and signed by the Chairman as correct. The report of the Directors was taken as read.

The CHAIRMAN then said: I am sorry to say that Sir John Pender is not able to be present to-day. He is suffering from what I hope is nothing worse than a severe cold; but it has prevented him from leaving his house. The revenue for the past year amounted to £22,593 as against £23,102 in 1893, or a decrease of £509. This is owing to our having received a smaller dividend for the current year from our investment in the Anglo-American Company. I regret to say that there is no visible improvement in the Atlantic traffic, and I fear that our income from that source is likely to continue to suffer for some time at any rate. The expenses for the year amounted to £1,301, as against £1,627, or a decrease of £326. This is mainly in consequence of the reduction in the number of our trustees, owing to the lamented death of our valued colleague, the late Sir James Anderson. I may mention that the cost of administering the Trust is £698 under the amount provided by the trust deed. Our revenue during the past year has been sufficient to meet two coupons of £3 each, and pay off an additional 5s. of the overdue coupon There still remains a balance of £1. 5s. in arrear, which we hope to pay about the middle of July next. I think I have now referred to all the important matters connected with the Trust. The decrease in income is to be regretted, but although the traffic in the Atlantic is very low at present, we may hope that with the return of business it will improve, in which case our income will be in a more satisfactory condition. With these observations I beg to move:—

"*That the report and accounts of the trustees to April 15, 1894, submitted to this meeting be and the same are hereby received and adopted.*"

Mr. J. DENISON PENDER briefly seconded the resolution, which was unanimously adopted.

On the motion of Mr. Shuter, seconded by Mr. Cunliffe Owen, the auditors—Mr. John G. Griffiths and Mr. John Gane—were re-elected for the ensuing year, at a remuneration of £25 each.

Mr. SHUTER then proposed a vote of thanks to the Chairman and the trustees.

Mr. W. H. BURMAN seconded the motion, which was unanimously adopted.

The CHAIRMAN acknowledged the vote on behalf of his colleagues and himself, and again regretted that the Chairman, Sir John Pender, had been unable to attend the meeting.

The proceedings then terminated

Norwich Electricity Company (Limited).

The third annual general meeting was held on April 24th, at the offices, Queen-street, Norwich, the Chairman (Mr. F. W. Harmer) presiding.

The CHAIRMAN moved the adoption of the report of the Directors, which contained the following :—" The arrangement which had been made with Messrs. Laurence, Scott and Co. to supply electricity to those who had previously used it, and also to any who might be desirous of doing so until the new machinery was ready to start, has proved a satisfactory one, since it has enabled the Company to commence operations with a sufficient number of customers to earn a profit from the very first day of its working. During the three months ending December 31st last the amount received for current has been £805. 15s. 8d., which will pay the cost of producing it, including salaries, wages, coal, and all other station expenses, the office expenses of the Company for twelve months, and the interest due to the bank, leaving a balance of £237. 9s. 10d., which it is proposed to carry forward. The rapid progress of the Company made it necessary for the Directors to obtain from Messrs. Gurney and Co. a further loan of £5,000, in addition to the £5,000 previously borrowed for the purchase of the Duke-street estate. Since January, however, shares to the amount of about £5,000 have been applied for privately, and the Directors are prepared to allot shares to a further limited amount, as it is clear that considerable extension will be necessary during the present year." The Chairman said the Directors would not have been suprised, nor do they think the shareholders could have complained, if in the establishment of a new enterprise like this the Company had for the first year or so lost money, but so far from this being the case, although it had only been at work for three months, it had not only paid its way from the very beginning, but had even realised a substantial profit for the past year. The Company had certainly made a capital start. The accounts came out better than they had any reason to expect, and they were very hopeful as to the future. They had got the best site in the city for their central station, which was a very important matter. They had adopted the system which they still thought was the right one, and their machinery was all new, and of the most modern and most improved construction. The adoption of the electric lighting in Norwich had gone on far more rapidly than they had expected, in fact, almost faster than they could deal with it; and it was only a question of a short time before the Company arrived at a dividend-paying stage.

The report having been adopted, the retiring Directors, Mr. C. R. Gilman and Mr. R. J. Colman, were re-elected; and Mr. J. Mottram was re-appointed auditor.

West India and Panama Telegraph Company (Ltd).

The following is the report of the Directors for the half-year ended December 31, 1893, to be submitted to the thirty-fourth ordinary general meeting, to be held at Winchester House, London, E.C., on Wednesday next, the 9th inst., at 12 noon :—

The amount to credit of revenue for the six months is £34,265. 6s. 4d. against £38,358. 11s. 9d. for the corresponding half-year of 1892, and the expenses have been £22,602. 8s. 3d. against £25,155. 11s. 5d. for the same period in 1892, leaving a balance of £11,662. 18s. 1d., which, with £4,137. 7s. 4d. brought from last account, makes a total of £15,800. 5s. 5d., with which it is proposed to deal as follows :—

	£	s.	d.
First Preference Shares—			
Dividend, six months to Dec. 31st, 6s. per share ...	10,368	18	0
Second Preference Shares—			
Dividend, six months to Dec. 31st, 6s. per share	1,400	14	0
Ordinary Shares—			
9d. per share (free of income tax)	3,312	0	9
Balance to current half-year's account	718	12	8
	£15,800	5	5

The traffic receipts for the six months show a decrease of £1,965. 4s. 3d. as compared with the correspoding period. It will be remembered that in June, 1891, certain reductions of rates were made in the West Indies. After an experience of two and a-half years it is estimated that these reductions have caused an aggregate loss of £20,863. This discouraging result again appears to show that reductions of rates on this Company's system are not compensated for by any increased use of the telegraph.

The cost of repairs to cables during the half-year amounted to £9,549. 6s. 10d., being £2,464. 0s. 5d. less than that for the corresponding period.

Since the issue of the last report the Company's second repairing steamer "Duchess of Marlborough" has been lying up in London, and up to the present the "Grappler" has dealt satisfactorily with all interruptions in the West Indies.

In accordance with the Articles of Association, Charles William Earle, Esq., retires at this meeting, and offers himself for re-election. The retiring auditor, John George Griffiths, Esq., desires to offer his firm, Messrs. Deloitte, Dever, Griffiths and Co., for election as auditors of the Company.

NEW COMPANIES, STATUTORY RETURNS, &c.

COMPANIES TO BE STRUCK OFF THE REGISTER.—The following concerns will be struck off the Register of Joint-Stock Companies within three months from April 27th, unless some reason be given to the Registrar for the non-filing of the statutory returns:—The Automatic Electrical Corporation (Limited), the Automatic Electric Supply Company (Limited), the British Electric Propulsion and Traction Company (Limited), the Electrical Works Construction and Maintenance Company (Limited), the Electro-Galvanic Machine Company (Limited), the New Electro-Amalgamator Company (Limited), the Portland Electric Light Company (Limited), Thompson's Electrical Fitting and Screw Cutting Company (Limited), the Wolverhampton Electric Light and Power Company (Limited), and Sharp and Co. (Limited).

"HARP" ARC LAMP SYNDICATE (LIMITED).—This Company was registered on May 1st, with a capital of £5,000, in £1 shares, to enter into and carry into effect an agreement which has already been prepared, and is expressed to be made between Wolstan Trubshawe of the one part, and the Company of the other part, to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat, motive-power, or otherwise; and manufacturers of and dealers in electrical apparatus and appliances of all kinds, and principally to carry on the business of an electric lamp manufacturing company in all or any of its branches. The subscribers are :—

	Shares.
Arthur Chester, 4, Kingsley-mansions, West Kensington, W...	1
Wolstan Trubshawe, 6, St. Benet-place, E.C.	1
John J. Rathbone, 78, Loftus-place, Shepherd's Bush, W.......	1
David Fowler, 6, East India-avenue, E.C.	1
Francis O. B. Reade, 83, Warwick-road, Earl's Court, S.W. ...	1
Thomas W. Bridgford, 2, Drapers'-gardens, E.C.	1
George F. Garry, 1, Westfield-road, Surbiton, S.W.	1

The first Directors are Arthur Chester, Vyoyar Trubshawe and Francis O. B. Reade.

CITY NOTES.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Particulars will be found elsewhere of the drawing of 111 debentures of £100 each of the Four per Cent. Mortgage Debenture Bonds of this Company. These debentures will be paid off at par on July 2nd, and interest will cease from July 1st.

AFRICAN TRANS-CONTINENTAL TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have issued their report, which is to be presented to the meeting to be held on Thursday next. The report states that it was originally proposed to raise a capital of £400,000, but that the Company was ultimately registered with a capital of £140,000 only, this being the estimated cost of constructing the line from Salisbury to Uganda. The report states that subscriptions for a substantial portion of this amount were received, but before proceeding to allotment, the Board obtained from Mr. Cecil Rhodes an agreement to subscribe for the balance at par, and now, when moneys are required, shares are allotted to Mr. Rhodes under this arrangement. The Directors decided to construct the first 400 miles of line between Salisbury and Zomba, in the Nyassaland Protectorate, and 200 miles of material were shipped to Beira for transmission to Salisbury and 200 miles for Zomba. The outbreak of the Matabele war upset the Directors' arrangements, and but little progress has been made with the Salisbury section; but the northern section has been proceeded with, and considerable progress has been made, no opposition but some help having been at first received from the Portuguese. Unfortunately, in February last the Portuguese officials placed obstacles in the way of the Company's works, and, rather than become involved in any conflict, the Company decided to cease operations, and have withdrawn their material for the present. The Directors consider that the action of the Portuguese is a direct infraction of Article II. of the Convention of 1891, under which the Company maintain they have a right to carry on their operations across Portuguese territory. Strong representations have been made to Her Majesty's Government in support of these views.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended April 29th were £901, as against £792 in the corresponding period of 1893, being an increase of £109. The total receipts for the half-year amounted to £15,513, as against £15,360 for the corresponding period of 1893, an increase of £153.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The Directors of this Company have resolved, subject to audit, to recommend to the shareholders, at the approaching general meeting, a dividend at the rate of £2 per cent. per annum, less income-tax, for the year ending March 31st.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of April are £3,900, as compared with £3,946 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—This Company's estimated traffic receipts for the month of April amounted to £1,742, as against £1,742 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of April, amounted to £56,751, against £56,469 in the corresponding period last year, an increase of £282.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of April, amounted to £38,802, and to £41,713 in the corresponding period of 1893.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The sixteenth annual general meeting of the shareholders of this Company was held at the offices, 19, Great Winchester-street, E.C., on Tuesday last. The total earnings amounted to £24,585. 7s. 3d., as against £23,989. 3s. 10d., an increase of £596. 3s. 5d., compared with the previous year, while the loss on exchange amounted to £16,563. 0s. 9d. The working expenses amounted to £8,606. 19s. 2d., as against £9,297. 9s. 7d., or a decrease of £690. 10s. 5d. Including the amount brought forward from 1892 (£588. 2s. 8d.), the balance to the credit of the revenue account was £16,566. 10s. 9d., from which was deducted £6,000 for debenture interest, leaving, after placing £1,000 to reserve, £9,566. 10s. 9d. The Directors recommended a dividend of £2. 10s. per cent. per annum (5s. per share) for the year, carrying forward £179. 10s. 9d. The Company's lines were reported in good working order. The Directors' report was adopted, and the dividend duly approved and declared. Mr. W. S. Andrews and Lord

Richard H. Browne were re-elected as Directors, and Messrs. Deloitte, Dever, Griffiths and Co. as Auditors.——It is announced that the offices of the Company will shortly be removed from 19, Great Winchester-street to Blomfield House, London-wall, E.C.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended April 27th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £2,825.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 834.—Vol. XXXIII. FRIDAY, MAY 11, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

It has been the politic custom hitherto for both electrical and gas engineers to aver that electric lighting would in no way affect the consumption of gas. Some figures recently published by an engineering contemporary would, however, appear to show that in London, at any rate, the large and rapid increase in the use of electricity which has been witnessed within the past two or three years has made a serious inroad into the income of the metropolitan gas companies. According to Field's Analysis, the average rate of increase of the metropolitan gas consumption between 1886 and 1891 was 947 million cubic feet, the increase for 1891 alone being no less than 1,313 millions. In 1892, however, the very year in which the London electricity supply companies first got fairly to work, the consumption of gas only increased by 35½ millions, and last year the curve passed through zero and became negative, the *decrease* amounting to 1,007 million cubic feet. Electricity, of course, is not the only competitor of gas, and the extended use of oil, the advent of an economical burner, and the rise in the price of gas have no doubt had much to do with diminishing the gas consumption per burner connected. But, on the other hand, it must be remembered that London ceases not to grow, some thousands of houses being added to it every twelvemonth, and that the use of gas engines and gas stoves has certainly not fallen off. Again, the brilliant weather of 1893 doubtless had something to say in the matter; but it will be observed that the actual decrease of 1893 followed hard upon a decided decrease in the rate of increase, and that the abnormal meteorological conditions of last year affected electricity as well as gas supply.

At the end of 1893 some 700,000 10-candle 35-watt lamps were connected to the mains of the London companies, and it is interesting to find that this decrease of over 1,000 million cubic feet in the London gas consumption would have been wiped out and converted into a healthy increase, had these electric lights been replaced by an equal number of equivalent gas burners. At the recent meeting of the Metropolitan Electric Supply Company, the district of which is a fairly representative one, it was stated that each lamp connected yielded a revenue of 8s. 9d., and with the Board of Trade unit at 7¼d. this means that each lamp must have been alight some 400 hours. Taking this as an average figure for London we find that these 700,000 10-candle lamps give the portentous total of 2,800 million candle hours. The tests of gas-burners recently published by us clearly show that with average London gas in an average burner 1 cubic foot per hour cannot be expected to give more than two candles. Hence the substitution of gas burners for these 700,000 glow lamps would have augmented last year's gas consumption by some 1,400 million cubic feet; no negligible proportion of the grand total. Moreover, when we consider the numerous large "isolated plants," such as those at the Hotel Metropole, Liverpool-street Station, Paddington, the Imperial Institute, the Palace Theatre, New Scotland Yard, &c., it is tolerably evident that the growth of electric lighting has had a good deal to do with diminishing the increase in the consumption of gas, and converting it, notwithstanding the continued growth of London, into a decided retrogression.

Mr. James Staats Forbes's speeches at the annual gatherings of the unfortunate shareholders of the London Electric Supply Corporation have generally been characterised by that dogged persistency, which we are pleased to consider as a peculiarly English trait, and also by no little originality. We doubt, however, if he has ever been quite so original in his views as on Wednesday last. For the Chairman of a concern which went all the way to Deptford and indulged in all manner of gigantic experiments with the plain and proclaimed intention of underselling all competitors, to complain of the inevitable result of the rate-cutting campaign his Company was the first to start is, indeed, strikingly original. But still more so is the Chairman's preference for the wasteful system of contracts as against the supply of current by meter. It is to be hoped that the London Electric Company will be chastened into living in amity with their meters as well as with their competitors.

In the eleven Papers which formed an intellectual feast for the members of the Iron and Steel Institute, electricity or magnetism is referred to in three only. One of these is remarkable as being, so far as we are aware, the first metallurgical Paper in which a Ewing hysteresis curve is given. The Paper is, however, by Mr. Hadfield, no ordinary metallurgist, and it seems that we have still to wait patiently for other makers of iron and steel to begin to pay attention to the magnetic properties of their manufactures. In a Paper by Prof. J. O. Arnold, it was observed that traces of carbon and sulphur appear even in electrolytically deposited iron. One Paper, that by Mr. D. Selby Bigge, was wholly concerned with electrical matters, and discussed the

Digitized by Google

transmission of power to tools in iron and steel industries. He advocates running separate circuits from each motor to the dynamo house, and that each circuit should be provided with an ammeter, under the eye of the man in charge of the engines. The author takes a sanguine view of the economy of electrical driving of factories, and cites some figures of the reduced coal consumption at Middlesbrough. He argues that the remodelling of old works on this system would "effect an enormous saving both in coal consumption, wages, and upkeep."

Mr. Vautin's Paper on the electrolysis of fused salts, a report of which is given elsewhere, is of interest as it marks a more hopeful attempt to grapple with the difficulties of molten electrolytes than has hitherto been made on an industrial footing. Destruction of the vessels and anodes and loss of the metal, which it is sought to obtain, by volatilisation or reunion with the anode product, have been the chief difficulties which the worker in this field has encountered. The use of a basic lining for the electrolytic vessel has much to recommend it, but the anode trouble may prove serious and has perhaps received less careful attention than the question of lining. A carbon anode even if dense and refractory is usually gradually disintegrated when immersed in a fused electrolyte, its life being shortened by alternate immersions and withdrawals. As we have before insisted, the makers of carbon electrodes have yet fields to conquer, and the production of a form of plate or rod at once refractory and non-pervious is a problem which they might well attack.

It is curious to note that the critical decomposing voltage for fused sodium chloride is found by Mr. Vautin to be about two volts. The voltage necessary for the decomposition of solid sodium chloride calculated from the heat of combination of sodium and chlorine is a little over 4 volts, whence it appears that the sensible heat requisite to fuse sodium chloride, must be capable of supplying a portion of the energy absorbed in its decomposition; or, in other words, that sodium chloride however heated to fusion, is about half way to the point at which it would dissociate. In estimating the commercial prospects of the process, it may be said that while the low voltage needed for electrolysis is a pleasantly small item on the debit side of the energy account, the heat supplied as such to the electrolytic vessel may prove a somewhat heavy charge. Fortunately, it always pays to replace electrical by heat energy, even at a lower efficiency. A third matter of some moment is the claim that was made by Mr. Cross in the course of the discussion on Mr. Vautin's Paper, that a wet process for the electrolysis of sodium chloride had an efficiency of 85 per cent. It may be taken for granted that the critical voltage for the decomposition of sodium chloride in aqueous solution is about 2 volts, as determined both by calculation and experiment. On the other hand, few, if any, wet processes have been actually worked with a smaller pressure than 4 to 5 volts. The method adopted for arriving at an efficiency of 85 per cent. from these data, is far from obvious.

The question whether certificates should be granted in the preliminary examination in Electric Lighting and Power Distribution, by the City and Guilds of London Institute, is opened in our Correspondence columns this week. Our correspondent thinks that certificates should be granted; and bases his belief on the fact that a very large proportion of the pupils who pass the preliminary stage would be unable to proceed any further. But, surely that is the very best reasons why certificates should *not* be granted. The examination is only a preliminary one, intended to sift off the duffers who would be sure to fail in the more serious subsequent stages, and who, if not sifted off, would become a great incubus on the examining body. It is only necessary that the student should receive an informal intimation that he has passed the preliminary stage; and if an official certificate, signed by high officers of the examining body, is granted to him, there is a great liability of his displaying the cardboard to the world as a guarantee of knowledge. The unsuspecting world would not stop to inquire *how much* knowledge, and the dangers of improper, and indeed fraudulent, usage would be very great. By merely publishing a list of preliminary "passes" at the examining centres, the City and Guilds Institute has done all that is necessary to inform the examinees; while, at the same time, it has safeguarded its own status and the interests of the electrical profession.

Since our leading article for this week was written, we have received the first number of "The Mathematical Gazette, a terminal journal for students and teachers." Of its eight pages, more than six are concerned with geometry, and one with arithmetical approximations. It is intended to confine this journal to elementary mathematics. The unexpected preponderance of geometry is accounted for by the fact that the Association for the Improvement of Geometrical Teaching, which has widened its basis so as to include all branches of elementary mathematics and mathematical physics, is adopting this means of furthering its objects. We wish it all success, hoping that, as a by-product of its labours, geometry itself may be developed.

The inclusion in our Leader last week of the anti-4πist among the body of screamers which fringes the outskirts of science does not imply, of course, that every anti-4πist is a screamer, nor that every anti-4πist can give anything approaching to a scientific reason of the faith that is in him. While, on the one hand, there are eminent scientific authorities whose objection to the constant 4π is both temperately stated and scientifically framed, there are, on the other hand, many who scream against the poor constant just because they love to scream, even though they know not any good reason for doing so. One of our American contemporaries, in a Leader on magnetic units, is strikingly original in the manner of its outcry against 4π, and it is as strikingly unscientific. "If, for example," it says, "our present system of linear measurements were based on π instead of on 10, then, while the ratio of the circumference to the diameter of a circle would become unity, the diameter would have to be expressed in terms of π." The fact that this particular sentence has been claimed by our contemporary to be a "slip of the pen," does not really affect the case; for, the

Digitized by Google

spirit of the above quotation runs through the entire Leader, and it emphasises itself again where the writer suggests "that π should be given the value of unity with respect to a circle." This is the worst, unkindest cut of all—and from an influential electrical paper, too! What a novel system of geometry would result, according to this showing, from the adoption of π as the radix of notation! For example, to travel all round a circle would involve a journey no greater than to traverse a diameter; while it would be only half as far to go by a semicircular route between any two points as to go by a straight line. Poor Euclid, thy glory hath departed!

Cambridge University Engineering Laboratory.—The new engineering laboratory will be opened on Tuesday, May 15th, at 3 p.m., by Lord Kelvin.

Personal.—We learn that Mr. C. Ashmore Baker, A.I.E.E., has established himself at 28, John-street, Bedford-row, W.C., in the capacity of consulting electrical engineer.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	Oct. 25th, 1893.
Bissao-Bolama	Nov. 24th „
Brest-St. Pierre (P.Q. Co.)	Mar. 29th, 1894.

Labuan-Hongkong Cable was opened for traffic on 7th inst.

Dynamo and Transformer Construction.—On the 29th inst. Mr. James Swinburne will commence a course of lectures to the students of the Electrical Standardising, Testing and Training Institution, on "Dynamo and Transformer Construction."

Richmond.—The Richmond Electric Light and Power Company have now commenced to work the whole of their plant, and are supplying a continuous current day and night. Fifty-three premises have already been connected with the mains, and are using lamps equivalent to 2,400 8-c.p. lamps.

Royal Institution.—At the general monthly meeting of this institution the special thanks of the members were returned for the following donations to the Fund for the Promotion of Experimental Research at Low Temperatures: Sir William O. Priestley, M D., £50; Sir David L. Salomons, Bart., £50.

The Heilmann Electric Locomotive.—The Heilmann electric locomotive drew on Wednesday a special train from the St. Lazare terminus (Paris) to Mantes, a distance of 33 miles, performing the journey in 55 minutes. The train was composed of five coaches and a break van, and at certain portions of the line a speed of 65 miles an hour was attained.

Charing Cross, Euston, and Hampstead Electric Railway.—This Bill, which proposes to enable the Company to acquire property for the purposes of the railway in Villiers-street, Buckingham-street, Oxford-street, and at Camden Town, came on Tuesday before the Committee presided over by Mr. Mellor, Chairman of Ways and Means, as an unopposed measure. The Committee passed the Bill, and ordered it to be reported for third reading.

Electric Traction at Bristol.—The opposition, which at one time threatened to become violent, to the proposal to construct an overhead wire electric tramway between Bristol and Kingswood, has at last subsided, and the Tramway Company's Bill will go before the Unopposed Bills Committee of the House of Lords. This enables the Tramway Company to push on with their preliminary arrangements, so as to start work at the earliest possible date, and we learn that estimates for portions of the contract have already been tendered.

Feeding the Turbines.—The *Birmingham Daily Post* announces to its readers that a benevolent Mr. Hadley had arranged to present the Worcester Corporation electric supply station with "a piece of land which was needed to feed the turbines." The gift is made on the condition that the banks of this piece of land are to be garnished with chestnut or mountain ash trees. The amount of land requisite for "feeding the turbines" is not stated, but we are glad to hear that the generous offer made by Mr. Hadley has been accepted.

Rheims.—At Rheims electric lighting plant has been erected in the gasworks, and the Brown dynamos, constructed by MM. Weyher et Richemond, are driven by gas engines, two of 50 H.P., two with two cylinders of 80 H P., and a single-cylinder engine of 45 H.P. The regular working of the engines has permitted, with the addition of an automatic starting arrangement of the electric accumulators being done away with, and the light is very steady, even when the motors only work with one-fifth of their full charge. The price of the kilowatt hour is nearly a shilling, but is to be reduced as the number of consumers increases.

Hull.—At a meeting of the Hull Town Council last Thursday week, the Electric Light Committee presented a proposal to reduce the price from 7d. to 6½d. per unit. In moving its adoption Dr. Holder (the Chairman) stated that they commenced by supplying 3,790 eight-candle lamps, and ended the financial year with supplying about 9,400. During the 11½ months 74,600 units were used. The present cost of production was 6¾d. per unit, but the increased consumption which ought to follow the reduction would, he thought, turn a trifling loss into a profit. During next year they hoped to be able to make a considerable reduction.

Corrosion of a Fagotted Iron Bar.—In the current number of *Engineering* there is an illustration of a curious example of corrosion of an iron bar. The surface of the bar is rusted, not uniformly, but in parallel streaks running the lengthways of the rod; these streaks giving the rod the appearance of having been built up of a number of parallel plates. Under the original test the bar, when new, gave no indication of lamination or fagoting, and the ultimate tensile strength proved to be 24·21 tons per square inch. But, after some months of lying about, the rod presented the curious appearance described. It is evident that the rod was originally made from fagoted iron, and the difference in electro-chemical condition of the alternate layers has given rise to oxidation only of the alternate positive layers.

Measurement of Inductance.—In the April number of the *Journal de Physique*, M. H. Abraham gives an account of a method for measuring self and mutual induction, which he says is capable of giving the quantity which is being measured to within one part in a thousand, the method employed consists essentially of balancing a steady current passing through one pair of coils of a differential galvanometer against a succession of induced currents sent, by means of a commutator rotating at a known speed, through the other coils. The commutator then being stopped, the secondary circuit, containing one pair of coils of the galvanometer, is connected with the extremities of a resistance r in the primary circuit. The value of r is altered till the galvanometer is undeflected, then, from a knowledge of the value of r and the speed of rotation of the commutator, the value of the mutual induction can be calculated. In many ways the method resembles that employed by Profs. Ayrton and Perry in their secohmmeter.

Technical Books.—The Cambridge University Press will shortly publish a treatise on the "Steam Engine and other Heat Engines," by Prof. Ewing; the seventh volume of the edition of Prof. Cayley's collected Papers, and the first volume of the collected Papers of the late Prof. Adams. An "Elementary Treatise on Electricity and Magnetism," by Prof. J. J. Thomson, is in the press, and also a new edition of Prof. Lamb's "Hydrodynamics," largely rewritten and extended. An "Elementary Treatise on Hydrostatics," by Mr. John Greaves, has just appeared, and a Key to Mr. C. Smith's "Arithmetic" is nearly ready. The completion of Mr. H. M. Taylor's "Euclid" is also announced, and will be published in August. In the series of Cambridge Natural Science Manuals, Mr. Glazebrook's volumes on "Light" and "Heat," recently published, will be followed by volumes by the same writer on "Mechanics and Hydrostatics," and on "Electricity and Magnetism." "*The Electrician*" Printing and Publishing Company will shortly publish a book on "Electric Lamps and Electric Lighting," containing Prof. Fleming's recent lectures at the Royal Institution.

Digitized by Google

London, Walthamstow, and Epping Forest Railway.—At the sitting of Sir John Kennaway's Committee, on Monday, Mr. Balfour Browne, Q.C., stated, on behalf of the promoters, that, having regard to the onerous terms which had been put upon them by the Committee at the instance of the London County Council of running workmen's trains at 1d. for nine miles, they were advised that it would be impossible to raise the capital for the line, and that if the proposal were insisted upon there was no alternative but to withdraw the Bill. He suggested that a suspensory clause should be inserted, so that those conditions should not apply until there had been some dividend paid upon the capital. The Chairman said that the Committee regarded the line of great importance, and hoped that some arrangement would be come to to obviate the necessity of withdrawing the Bill, and the proceedings were adjourned till after Whitsuntide to enable the promoters to further negotiate with the County Council. Although alternative powers for the use of electricity are provided for in the Bill, we understand that it is the present intention of the promoters to use steam as the motive power.

The London County Council and Technical Education.—It is announced that, with a view to promoting a better understanding of the needs and desires of the various trades in the matter of technical education, the Technical Education Board of the London County Council propose to hold, during the months of June and July next, a series of public conferences between the representatives of the principal London industries. Each conference will be strictly confined to representative practical men belonging to one particular group of trades. Every trade union belonging to the group will be asked to nominate delegates. Every employers' association will be similarly invited. The London Chamber of Commerce and the London Trades Council will also be asked to designate other representativn employers and workmen. The meetings will take place from 8 to 10 p.m., probably at the County Hall, Spring-gardens, on dates to be subsequently announced. The first meeting will be devoted to the building and furniture trades. The three subsequent meetings will follow at fortnightly intervals, and will deal respectively with the engineering, shipbuilding, and metal trades; the book, paper, and printing trades; and the clothing, leather, and miscellaneous trades. The names and addresses of representatives should be sent at once to Prof. Wm. Garnett, Secretary of the Technical Education Board, 13, Spring-gardens, S.W., from whom any further particulars can be obtained.

Transmission of Power.—The Government of Holland invited last year plans and tenders for the construction and delivery of the motive power for the new sea locks of Ymuiden, the seaport of Amsterdam. The plant, says *Engineering*, was to consist of the machinery for 12 lock gates, 24 sluice valves in these gates, 12 sluice valves for bypasses, and 12 capstans. Machinery for the lighting by electricity of the surroundings of the locks was also to be provided. The subscribers were at liberty to tender either for electric or hydraulic machinery. In all some 13 plans were submitted, viz., eight for hydraulic machinery, four for electric machinery, and one for compressed air machinery. The Government has now decided that none of the plans submitted are entirely satisfactory as they stand, but have nevertheless purchased the following schemes: For electric machinery: 1. The plans of Messrs. Gebrs. Figee, engineers, at Haarlem, and Mr. P. H. ter Meulen, electrical engineer, at Amsterdam, agent of the Electrizitäts-Actiengesellschaft formerly Messrs. Schuckert and Co., at Nuremberg, Germany, for the sum of 1,200 guilders. 2. The plans of Messrs. Siemens and Halske, of Berlin, for 700 guilders. For hydraulic machinery: 1. The plans of Messrs. C. Hoppe, engineers, at Berlin, 1,200 guilders. 2. The plans of Sir W. G. Armstrong, Mitchell, and Co. (Limited), at Newcastle-upon-Tyne, for 700 guilders.

Electric Railways and Tramways.—At a meeting of the King's College Engineering Society, held on Friday, April 20th, Mr. Makovski delivered his presidential address on "Electric Railways and Tramways." He commenced his Paper by dividing the methods of conducting into three primary divisions—the overhead, the side rail, and the centre rail system. Each of these divisions could be subdivided by employing a separate rail for return current. He also mentioned that a variation of the last method was to have a centre rail in a conduit under the ground. Of the first system he took the Molding Bouhl Railway as a type, and described the inverted tube with slit used in connection with the boat for carrying the current, which he also described. Next followed descriptions of the trolley-wheel contact with overhead solid wire, and Mr. C. T. Brain's method of enclosing the conductor in a conduit with a cover, which is of steel, and raised and lowered by rails on the contact maker. Mr. Makovski then gave details of the City and South London plant, more particularly the direct-driving motors, in which the armatures are wound upon the axles. The Portrush Railway, in which the motive power is obtained through turbines, and the Mont Salève Railway were then described. The latter is a rack railway with a gradient of 1 in 4. Next followed interesting details respecting the relative merits of overhead and other conductors, also of direct as opposed to gear-driving.

Joule's Equivalent of the Heat Unit.—"In whatever way," says a correspondent of the *Engineer*, "the determination of the value of J is approached, there are three constants whose values must always be determined—(1) the value of g; (2) the temperature coefficient of the specific heat of water; and (3) the thermometric scale. This last usually involves the reduction from mercury in glass to perfect gas thermometers. In 1878 Joule published his last research on the numerical value of J, and gave $J=774{\cdot}6$ (not 772, &c.). This, by the application of Regnault's formula for the specific heat of water, was reduced to 772·5. In 1880 Rowlands redetermined J, and paid special attention to points (2) and (3) above; he also compared Joule's mercury thermometers with his own air thermometer, and gave the corrections on Joule's figures, both on this account, and also for the difference in the specific heat of water, as determined by himself and by Regnault. Rowland's work has lately been confirmed by Griffiths—1887 to 1892. In *Science Progress*, April, 1894, Griffiths sums up, 'our present knowledge of the value of the mechanical equivalent' and recommends that $J=778$ be now adopted." It is scarcely probable that writers and others will forsake the old-fashioned 772·5 for the newer determination, until engineers and scientists have held a Congress over the matter and decided on some universal value of the constant. Until that happens we may comfort ourselves with the reflection that the difference between the two values is less than one per cent.

Dynamometry.—Dr. Louis Duncan, writing in the *Electrical World*, of New York, says:—"The transmission dynamometer which I am going to describe has been found useful for some special experiments for a number of years. I have used an absorption dynamometer, consisting of a copper disc rotating in a magnetic field. The power was calculated from the pull on the magnet and the speed of the disc. The heat was absorbed by water running through the apparatus. This dynamometer is of a rather limited range, unless belting is resorted to. For the purpose of trying some experiments on the efficiency of air propellers, a transmission dynamometer was designed on somewhat the same principle. It consisted of a copper disc fastened to the propeller to be rotated and placed in the field of a rotating electromagnet. The apparatus was calibrated by turning the magnet at known speeds and measuring the pull of the disc, which was kept stationary. After this, to measure the power transmitted, it is simply necessary to know the speeds of the field magnets and the copper disc, and the pull is proportional to the difference of the speeds, and can be obtained from the calibration curve. The disc is so constructed that it can be cooled by allowing water to flow on it in such a manner as not to absorb power, and a temperature correction can be applied if necessary. The speed of the disc can be regulated by varying the speed of the magnets and the strength of the magnetic field. In this way power can be transmitted without the intervention of any belt or gearing, and it forms an exceedingly convenient apparatus for some purposes."

Magnetic Measuring Instruments.—At a recent meeting of the Academy of Sciences of St. Petersburg, says *Nature*, Dr. S. Wild read an interesting Paper on some improvements in the design and construction of magnetic instruments. The Paper is divided into four parts, the first containing the results of some experiments which show that metallic wires are preferable to the silk threads usually employed for the suspension of the magnets in magnetographs. The second part deals with the question of the accuracy of the readings given by the instruments employed to record the variations in the magnetic elements, when these instruments are contained in buildings composed of a material (such as ordinary red brick) containing iron. The experiments on this subject, commenced in 1878, have been continued, and show very clearly that a brick building has no influence on the measurements of the strength of the field, while the influence on the dip is quite negligible. The above result has also been deduced theoretically by M. Chwolson by means of the known value of the susceptibility of the bricks. The third part of the Paper contains a description of a small magnetometer for determining the value of the horizontal component of the earth's magnetism, designed for the use of travellers in countries where it would be difficult to carry the ordinary instruments. The instrument fits on Hildebrandt's small universal theodolite, which instrument is fitted with a compass. The combined instrument, although of small weight, is capable of giving results of considerable precision. Thus the dip can be determined to within half a minute of arc, and the horizontal component to within one part in four thousand. Lastly, the Paper contains a description of some changes which Dr. Wild has introduced into the portable magnetometer.

Introducing the Quadruplex into England.—In a letter to the *Electrical Engineer* of New York, Mr. Gerritt Smith gives, *apropos* of Mr. Preece's "Notes of a Trip to the United States and Chicago, 1893," the following account of the introduction of the quadruplex into this country :—

In view of the openly expressed doubts as to the success of the system abroad, the trial was looked upon as purely in the line of experiment ; and predictions were freely made that stormy weather, with the usual accompaniment of a London fog, would prove an effectual barrier to its successful working. It was therefore with considerable pride that from time to time during the first week or two, information was communicated to Mr. Preece of the satisfactory working during weather that proved almost too much for the duplex circuits between London and Liverpool ; but these occasions served to indicate what might be expected when the now anxiously looked for London fog should arrive. The patience of my faithful co-operator at the Liverpool end was soon rewarded by the arrival of a storm from across the Atlantic bringing with it conditions for the development of a veritable London fog which reached a maximum density about 11 a.m. when even the street traffic was rendered somewhat perilous. The service with Liverpool opened rather tardily upon all the regular circuits, the quadruplex being the exception. It was at once supplied with business for all sides owing to the partial suspension of other circuits. At about 10 o'clock a.m. the various duplex circuits between the London and Liverpool exchanges and main offices began to fail, and at 11 o'clock the condition of circuits had arrived in which it was deemed useless to attempt further working, and with the various Liverpool files well filled with business awaiting transmission the following memorandum was dropped to Mr. Preece : "11 a.m., Liverpool duplexes all suspended work. Quadruplex working finely four sides." In less than five minutes Mr. Preece came to the operating room accompanied by Mr. Patey and a sufficient number of the officials from the various departments interested to form a complete circle around the quadruplex table, at which four operators were easily working, two sending and two receiving. Among the group also was Sir William Thomson, whose interest in the exhibition was clearly shown by earnest inquiries respecting details of the service, condition of the line, &c. The experimental stage having been so successfully passed, the incident above narrated is put on record as part of the heretofore unpublished history of the introduction of multiplex telegraphy abroad ; I will simply add thereto the following clipping from the *Telegraphic Journal* of December 1, 1877, as follows :—"The quadruplex instruments continue to work excellently well between London and Liverpool. There can be no doubt that the system is a perfect success. Messrs. Gerritt Smith and Hamilton who have so ably superintended the setting up and working of the apparatus have returned to America."

Electric Heating for Street Cars.—The use of electric heaters in America for street cars propelled by electricity has already passed the experimental stage. They have been demonstrated during the past two winters to be both electrically and commercially successful, and are now very generally adopted all over the country by street railway companies. At the present time over 200 electric street railway lines in the United States are equipped in whole or in part with electric heaters. Comparative tests have been made between the electric heaters and the coal stove, and with most satisfactory results. The cost of operating electric heaters depends upon the cost of current, and this varies greatly in different localities. The average cost, however, per car day is about 25 cents. At Niagara Falls, N.Y., the street railway company has 38 electric heaters in operation on its cars. The extra cost per day for coal burned to generate electricity to operate the heaters is 75 cents, and it is estimated that the total cost per car day is 18½ cents, or about 5½ cents in excess of the cost of operating coal stoves. During last winter the Central Electric Heating Company have made an elaborate series of tests on the cars of various roads equipped with their heaters, in which thermometers were placed in various positions inside the car and on the platforms. These show that the electric heaters maintain the temperature at from 25deg. to 30deg. above that of the outside air, but what is most important, maintain an *even* temperature over the entire car. Thus on a test made on the Atlantic Avenue Railroad, Brooklyn, N.Y., on Feb. 24th, on an 18ft. car, the outside temperature for the trip averaged 7°F., while the temperature inside the car averaged 39°F. Only four heaters of the "B" style were employed and the current averaged 5⅓ amperes, which at the average E.M.F. of 436 volts on the line, shows the low consumption of 2,325 watts. On another test with the outside temperature averaging 28°F., the car was maintained at over 55°F. It is claimed by Mr. Silliman, electrical engineer of the Atlantic Avenue Railway Company, that the extra space obtained in their cars by using the American electric heaters more than pays for the extra amount of current consumed to operate them, and that these cars have been quite warm enough, even in extreme weather.

Electric Discharges through Gases.—In the course of his recent Friday evening discourse at the Royal Institution, Prof. J. J. Thomson, who took as his subject "Some Properties of the Electric Discharge through Gases," devoted his first experiments to showing the apparent reluctance of the electric discharge to pass from a gas into a metallic electrode. In one of the experiments by which he illustrated this a bulb was employed into which two long electrodes projected. The discharge between these was not from point to point, but from the point of one to the base of the other. He then showed how the states of electrification in a bulb through which an alternating current is being passed vary according to the gas and electrodes used. Oxygen gives a strong positive electrification, while with hydrogen it is different in different parts of the bulb. The discharge from an electrode of oxide of copper in hydrogen is negative till the oxide is reduced, when it becomes positive. Prof. Thomson then went on to consider the discharge through gases without metallic electrodes, and for this purpose used the rapidly-alternating current produced by the discharge of two Leyden jars, connected with a Wimshurst machine. The discharge wire was made into a coil, in the centre of which were placed bulbs containing the gases to be experimented upon. When two gases were to be compared in respect of conductivity, &c., the wire was made into two coils, in one of which the gas to be tested was placed and in the other a standard bulb. The brightness of the discharge in the latter gave an indication of the amount of energy absorbed by the former. From this and other experiments, the lecturer deduced the conclusion that the conductivity of gases at a certain degree of rarefaction is greater than that of any metal, and almost infinitely greater molecule for molecule. At a higher degree of rarefaction, however, conductivity is diminished, and in a perfect vacuum, as has been shown by some of Prof. Dewar's experiments, it is probable that the discharge as such would not pass at all. Prof. Thomson showed that when a vacuum bulb was enclosed in a vacuum jacket which had been made with mercury and the whole apparatus placed inside a coil, the discharge occurred only in the inner bulb. But upon increasing the density of the mercury vapour in the annular space, the discharge took place there instead of in the inner bulb. The last experiment performed referred to the influence of a magnetic field on the discharge, which was shown to take place more easily along the lines of magnetic force than across them.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 713, Vol. XXXII.*)

Furnaces and Boilers.

Draught.—We shall now enter into a more particular study of the working of steam generators, and will commence with some important questions relating to the furnace. Of these latter, one of the most important is the question of draught, *i.e.*, the proper supply of air to the incandescent and gaseous fuel in the combustion chamber. We shall find it convenient to consider two classes of draught: the induced or vacuum draught, and the forced or plenum draught.

Induced Draught.—Induced draught occurs where the products of combustion are drawn through the flues, and air is thereby led into the combustion chamber by means of a sucking action, *i.e.*, by lowering the pressure of the gases below that of the atmosphere at the end of the flues at which the gases are discharged. This class of draught is produced by the chimney, or the so-called natural draught, as well as by the steam blast.

Forced Draught.—Forced draught occurs where the products of combustion are driven through the flues against the atmospheric pressure and the frictional resistance of the flues, by virtue of a supply of high pressure air at the entrance end of the flues; it is therefore due to a positive rise of pressure above that of the atmosphere at the fire end of the flues. In a purely induced draught the pressure in the flues is everywhere less than that of the atmosphere, or a partial vacuum is produced; while in a purely forced draught the pressure in the flues is everywhere greater than that of the atmosphere. It will be noticed that in the former, cold air will rush into the flues through every accidental or intentional opening in the flues, such as through the fire door or through pores in the brick setting; while in the latter, on the other hand, cold air will never tend to rush in through openings, but hot gases will tend to rush out of them. In many boiler plants a combination of induced and forced draught is used; while in others it is often the practice to use chimney draught on ordinary occasions, and to assist this by forced draught when a larger supply of air is required. Various forms of blowers are used for forcing draught into the flues. With a combined forced and induced draught there will be a positive pressure in the early parts of the flues, and a partial vacuum in the later parts. If the forced draught is not vigorous, and is applied beneath a thick fire, it may happen that there will be vacuum everywhere beyond the grate.

Draught Gauging.—It is the usual practice to express the value of a draught in terms of the number of inches of water which give an equal head, or pressure; and a water-gauge is commonly employed for determining the draught. This gauge consists of a bent glass tube, forming a **U**-tube with one limb bent horizontally, and the other prolonged vertically. The horizontal end is placed in direct communication with the part of the furnace where the pressure or vacuum is to be measured, and the other end is open to the air. Water is placed in the bend of the tube. Fig. 10 shows the action of such a gauge; on the right hand, when there is a forced draught, and on the left hand when the draught is induced. It will be seen that the amount of vacuum in inches of water is shown by a depression of the water in the straight limb of the gauge G, while the amount of plenum, or pressure above the atmosphere, measured in the same manner is shown by the amount of forcing of the water column up the vertical limb. The head is, of course, represented by the difference in horizontal level of the surface of water in the two limbs of the gauge. To avoid inequality in surface tension effects at the surface of the water, it is well to arrange that the water level does not fall to the bent portion, W, of the tube. We shall find it convenient to represent any draught due to vacuum by a negative sign prefixing its value; while a positive sign will represent draught due to plenum. The total draught in a system of flues may not be capable of measurement at any one place; for it is evidently represented by the difference of pressure, reckoned algebraically, between the entrance and outlet of the flues. All that the gauge tells us is the effective pressure at any one place, as measured above zero pressure, *i.e.*, the atmosphere. It is like an electrostatic voltmeter connected between earth and one point of an electric circuit; it may tell nothing of the motive force. In the case of a simple draught, *i.e.*, of one produced wholly by induction or by forcing, the total draught *can* be indicated on the gauge, if the proper place be selected at which to fix the gauge. This place is the point where the draught is applied—at the base of the chimney in induced draught, or by the blower twyer, where the air enters the flues, in forced draughts. But if the draught is not simple, being due to both induction and forcing, the gauge must be fixed first at the entrance to the flues, then at the exit from the flues, or two gauges may be used simultaneously; the algebraic difference of the two values giving the total draught propelling the gases. It is often instructive to take an indication on the gauge at intermediate points in the flues, with a view to finding how the draught is distributed. Throughout the length of the flues there is a continual fall in absolute pressure, due to flue friction, change of speed of the gases, and so on. By carefully gauging the flues at a number of points, it is often possible to detect sources of inneconomy in the distribution of the draught.

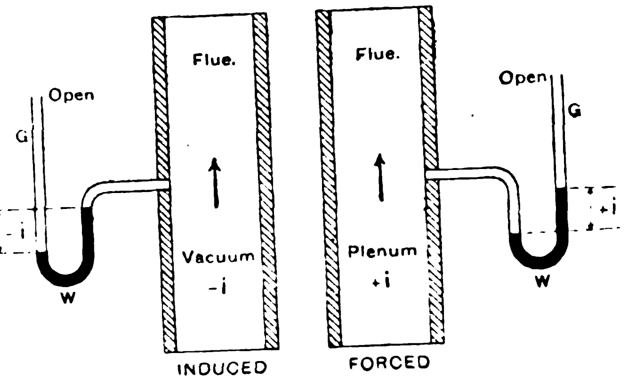

Fig. 10.

Amount of Draught.—Ordinary furnaces are usually worked at full load under a head equal to from ¼in. to 1¼in. of draught, rising sometimes to 1½in.; and an average draught in furnaces used in large electric power stations may be taken at from ½in. to ¾in. The amount of draught required in a boiler plant depends upon several considerations, of which the following are the most important:—(1) The quality and thickness of the fuel on the grate; (2) the area of the grate; (3) the length of the flues; (4) the surface exposed to the moving gases in the flues; (5) the velocity of the furnace gases; and (6) the requirements of rapidly getting up steam, or of extra rapid steaming for short intervals. Other things being equal, ordinary slack requires 25 per cent. higher draught than round steam coal, and should never have less than ½in.; round anthracitic coal requires from 80 to 100 per cent. more draught than round steam coal, coke breeze 50 per cent. more, wood and straw about 50 per cent. less. Town refuse requires nearly 2in. of draught for its satisfactory combustion.

Chimney Draught.—A chimney of not less than a certain height is always required by the local authorities to be used in conjunction with electric power stations, in order that the products of combustion may not become a nuisance in the neighbourhood. The chimney, therefore, forms a readily available method of supplying air to the fuel. Chimney draught, however, cannot be had for nothing, neither in regard to prime cost nor to the expense of constant running. To run a chimney draught, the escaping gases must be passed into the chimney at a high temperature; they will, therefore, represent a certain percentage of heat expended, or a certain number of tons of coal consumed per annum solely to keep up the draught. Chimney draught is caused by the difference in elastic pressure

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

of the atmosphere and of the column of hot gases in the chimney, as measured at the bottom of the chimney; this difference arising from the lesser specific density of the hot gases, owing to their heated condition. The exact measure of the difference of pressure—*i.e.*, of the head—is equal to the difference in weight of a column of cold air equal to the height of the chimney and a column of the hot gases of the same height, the sectional area of both columns being unity. For any given average temperature of hot gases in the chimney, therefore, the draught produced will be simply proportional to the height of the chimney. On the other hand, for any chimney of given height, the draught will be proportional to the difference of the densities, and will, therefore, increase in direct but not simple proportion with the absolute temperature of the hot gases. Measured in inches of water, the theoretical value of a chimney draught is expressed by the formula:—

$$-i = 7\cdot6\,H\,\frac{T_2 - T_1}{T_2\cdot T_1}, \quad . \quad . \quad . \quad . \quad (79)$$

where H is the height of the chimney in feet, T_2 is the absolute temperature of the chimney gases, and T_1 is the absolute temperature of the atmosphere.

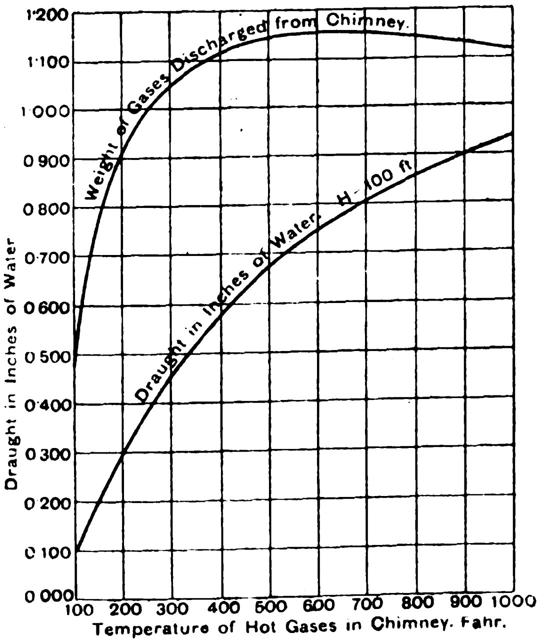

Fig. 11.

This equation is represented by the lower curve in Fig. 11, in which the ordinates measure inches of water and the abcissæ measure the temperature (on the ordinary scale) of the gases, the temperature of the air being taken at 60°F. The sectional area of the chimney does not enter into the formula, but, if the area is too small at the top, the draught will be seriously reduced. Again, the sudden check in the speed of the gases as they issue from the orifice into the air, will produce a back pressure and reduce the draught. The formula is calculated on the assumption of a still atmosphere, while experience shows that the liveliness of a chimney draught is enormously modified by the direction and force of the wind.

The purpose of a chimney is not merely to produce a certain number of inches of draught; it is further required to discharge a certain number of pounds of hot gas. We have seen that in proportion as the gases are at a high temperature in the chimney, the draught increases, but in like proportion will the volume of gas to be discharged become greater. Moreover, while the volume of the gases representing so many pounds of products of combustion rises in simple ratio with the absolute temperature, the draught rises at a decreasing rate, as is seen in Fig. 11. Consequently, there will be a certain temperature beyond which the power of the chimney to remove the gases will increase at a less rate than the bulk of material to be removed. It is manifestly a useless expense to allow the gases to escape at any higher temperature than this limit. Rankine has shown* that the weight of material removed by a chimney, acting alone and without forced draught, is proportional to

$$\frac{\sqrt{(0\cdot96\,T_1 - T_2)}}{T_1} \quad . \quad . \quad . \quad . \quad (80)$$

This expression becomes a maximum when

$$T_2 = 2\tfrac{1}{12}\,T_1. \quad . \quad . \quad . \quad . \quad . \quad (81)$$

Accordingly, with cold air at 60°F., the most effective temperature for the gases in the chimney will, theoretically, be about 600°F. At any other temperature a larger chimney would be required in order to do the same work. The variation of the function given in equation (80) is shown by the top curve in Fig. 11. It will be seen that, while this function is a maximum at about 600°F., it is not sensibly of lower value at neighbouring temperatures, and that even at 300°F. it is not more than about 4 per cent. of lower value. The output of the chimney is practically the same whether we allow the gases to escape at 600°F. or at only 300°F. On the other hand, the amount of heat permitted to escape with the gases is very much less at the lower than at the higher temperature. If we assume a specific heat of 0·25 for the hot gases, there will be no less than 75 B.T.U. reclaimed per pound of gas, or

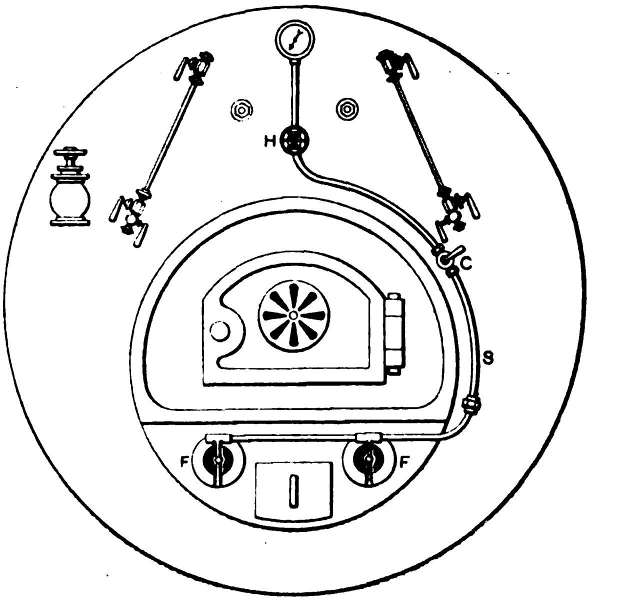

Fig. 12.

from 1,500 to 2,000 B.T.U. per pound of coal burned, by allowing the gases to escape at the lower rather than at the higher temperature. The element of working economy introduced thereby is by no means inconsiderable, and may represent a saving of many hundreds of pounds in the annual coal bill, in a large power station. It is true that by adopting the lower temperature we shall reduce the draught of the chimney; but that is remedied at little extra cost, by building the chimney a few feet higher. The economy of heat cannot well be carried below about 300°F., for at lower temperatures than this the gases would be but little hotter than the water they are required to heat. It should be pointed out that by increasing the economy the weight of gases to be discharged will be decreased, enabling a chimney of lesser section to serve the purpose equally well. Under ordinary conditions, a well-built chimney of 134ft. height will give one inch of water of draught, and the draught with any other height will be simply proportional to the height.

Meldrum's Forced Draught.—A form of under-grate forced draught which has been found very economical in some electric power stations is that known as Meldrum's forced draught. This invention is practically a live steam blast applied, not at the chimney end of the flues, but under the grate; and it consists of a nozzle supplied with steam from the boiler, and an

* Rankine: "Steam Engine and Other Prime Movers." 1885. Page 289.

Digitized by Google

annular orifice communicating with the air, through which air is drawn by the vacuum produced by the steam blast. Both air and steam are forced into an expanding funnel, in which their motion is efficiently slowed down, and are discharged immediately below the fire-bars. Two of these air-injectors are usually placed under each grate. Fig. 12 gives a sketch of the steam connections for the apparatus, at the front of the boiler. The expanding funnel is shown at F, and the steam pipe leading to this at S. The supply of steam is regulated by the handle H, and may be shut down at any moment by the cock C. It will be seen that the ashpit is closed; but the fire-door may be opened for stoking by hand. Where a very high draught is used it is sometimes customary to close the cock C before stoking; and this must, of course, be done when removing ashes. The Babcock & Wilcox boilers at the West Brompton station of the House-to-House Electric Supply Company are fitted with these draught generators; and at this, as well as at other stations, a considerable economy of fuel and increase of steam production have been realised. In some other systems of forced draught by steam induction, such as that invented by Mr. D. K. Clark, the air and steam are admitted over the grate, the jet being directed towards a point immediately behind the bridge. The ash-pit is then left open, but the fire-door must remain closed while the blast is in action. This form of over-grate draught is usually employed as an auxiliary, to be used only just after stoking in order to supply air to the volatilised fuel, and thereby prevent imperfect combustion. One of the difficulties attending the use of forced draught is the melting of the fire-bars by the intense local heat. This difficulty renders it inadvisable to apply forced draught to ordinary grates, except where only a moderate draught is required. In the Meldrum furnace each fire-bar is locked to the next by a series of lugs or pins fitting into slots on the adjacent bar; so that it is impossible for any bar to be lifted above the level of the grate, and melting is thereby reduced to a minimum.

(To be continued.)

MAGNETIC QUALITIES OF IRON.*

BY J. A. EWING, F.R.S., AND MISS HELEN G. KLAASSEN.

(Concluded from page 8.)

A more striking example of the influence of the molecular shaking which is brought about by reversals of a magnetising force will be found in the experiment of Fig. 32. This experiment, like the last, was made with a magnetic curve tracer in which the metal under examination had two independent magnetising coils wound on it. Through one of these, Q, a current was passed which, when acting alone and carried through a cycle of values, gave the usual curve, *a b c d*, the dotted line, *a b*, being obtained after the metal had been neutralised by reversals in the usual way. Next the current in Q was brought to some steady value, and a violent molecular shaking was produced by rapid reversals of a current in P, which, starting with a rather high value, was gradually reduced to zero, while a rapid reversing key in its circuit was kept in motion. It would be inappropriate to call this process by the accustomed name (of "demagnetising by reversals") inasmuch as its effect was to leave the iron more or less strongly magnetised in consequence of the existence of the constant magnetising force due to the current in Q. The maximum magnetising force produced in this process of reversals by the current in P was about equal to the maximum force which was excited by the current Q at the extreme point, *b*, of the curve. Reversals of a force beginning with this high value and decreasing to zero gave the metal so thorough a molecular shaking up that the magnetising effect of the steady current became, under their influence, almost wholly independent of the previous magnetic history of the piece. In other words, the effects of hysteresis nearly disappeared. The points marked thus + in Fig. 32 were obtained in this way. They represent the relation of B to the magnetising force after reversals of an auxiliary force had been used to produce violent molecular agitation. Some of the points are marked thus •, and in these cases the process of magnetic shaking was performed after the steady current had been so manipulated as to lead to a point on the descending limb of the ordinary cyclic curve; the application of reversals then brought the magnetism down to the marked value. On the other hand, the points marked + were reached by applying reversals to raise the magnetism from a point on the ascending limb of the main cycle. It will be seen that the points marked • lie as nearly as possible on the same smooth curve with those marked +. That is to say, the effects of hysteresis are obliterated by this method of agitating

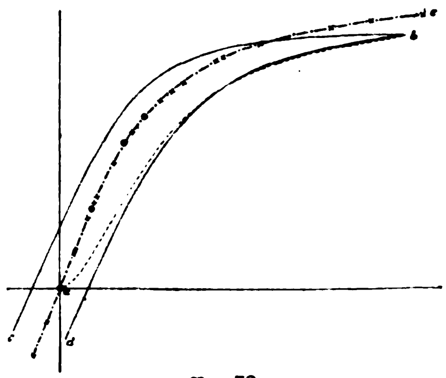

Fig. 32

the metal even more completely than they are obliterated by mechanical vibration in soft iron.* Ascending and descending limbs alike become merged on the single curve *a e*.

Reference has been made above to the evidence of time-lag in magnetisation which the magnetic curve tracer furnishes. It is in the softest iron that these are most apparent, and especially when the pieces under test are solid or imperfectly laminated. When solid rods of soft iron are used, three quarters of an inch or so in diameter, the movements of the mirror of the curve traces take place as if it were controlled by a dash-pot, or were immersed in a viscous fluid. Even a comparatively slow gradual change in the magnetising current is followed, after it ceases, by a continued creeping of the reflected spot of light lasting for some seconds,† and, when a cycle of reversal is performed at even a very moderate pace, the curve assumes a wholly different form from that which would correspond to a quite slow process. This is illustrated by Fig. 33, where (*a*) is the curve taken quite slowly for a pair of soft iron rods 1·9cm. in diameter, and (*b*) and (*c*) show the results when the period of a cycle was 3sec. and 0·43sec. respectively.

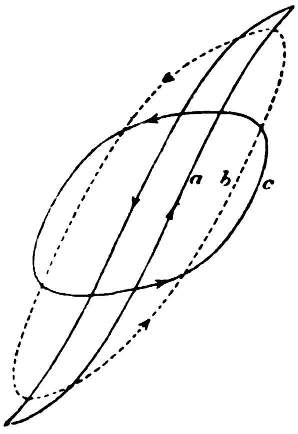

Fig. 33.—Magnetic Curve Tracer Curves for Soft Iron Bars. *a*. Cycle performed slowly; *b*. Period of Cycle, 3 seconds; *c*. Period of Cycle, 0·43 second.

Digitized by Google

The influence which even the lower of these speeds has on the form of the curve is extraordinary. The maximum of the magnetising current is nearly the same in all three curves (owing to the self-induction of the magnetising coil it is a little less in the faster cycles, but enough non-inductive resistance was put in the circuit to make this difference small). It will be seen that the effect of time-lag in lowering the maximum of magnetisation (namely, the maximum of the mean magnetisation taken over the cross-section of the rods) is enormous, the effect of change in frequency being most noticeable when the period is comparatively long. Again, the influence of time-lag in augmenting the work spent in magnetic reversals is conspicuous, and here, again, it is remarkable how great this influence is at very moderate speeds of reversal. The exact form which the curve takes at any assigned speed will, of course, depend on what particular function of the time the applied electromotive force is caused to be, as a consequence of the exact form of the commutator plates and other conditions of the experiment. In the present case it appeared that the applied electromotive force was made to vary rather quicker near its mean values and rather less quick near its extreme values than would have been the case had it been a simple harmonic function of the time.

It is noticeable that the area of the curve increases at first and finally decreases as the frequency is increased. In other words, with a given maximum of magnetising current the work expended in reversals is a maximum, per cycle, for some one frequency. This, of course, results from the fact that at higher frequencies the magnetisation fails to penetrate sufficiently into the interior of the bar.

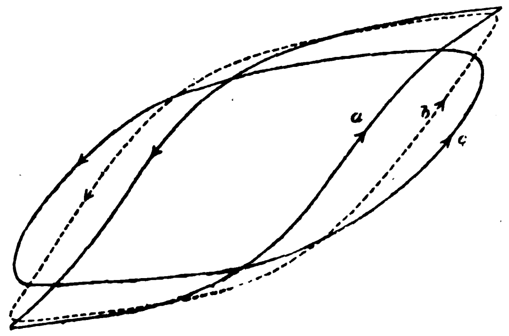

Fig. 34.—Magnetic Curve Tracer Curves of Steel. *a.* Cycle performed slowly; *b.* Period of Cycle, 3 seconds; *c.* Period of Cycle, 0·6 second.

In steel these phenomena are much less apparent than in soft iron, but they take place to some extent. Fig. 34 shows the results of a similar experiment made with a pair of bars of tool steel of the same dimensions as the iron rods of Fig. 33 Here again (*a*) shows the effects of perfectly slow reversal, while (*b*) and (*c*) are cycles performed in periods of 3sec. and 0·6sec. respectively. In both of these experiments (Figs. 33 and 34) the cycles marked (*b*) and (*c*) were produced by using an electric motor to drive the commutator, regularity of speed being essential to steadiness of the figure, especially at the slower speeds.

Whether these manifestations of time-lag in magnetisation are entirely explicable by reference to Foucault currents is not easy to answer. It appears possible that another cause may contribute to produce time-lag. In the upsetting of a group of molecular magnets time is needed for the disturbance to gradually spread from the point, or points, where the mutual controlling forces which produce equilibrium are first overcome. Let a group of pivoted compass needles, for example, be subjected to a gradually augmented deflecting magneting force; the first to yield will in general be some outlying member; its yielding will reduce the stability of its neighbours, and the disturbance spreads to them and from them to others. In a bar of iron we may conceive the molecules next the surface to be less strongly controlled than those in the interior, and to be, therefore, more likely to act as origins of disturbance when the equilibrium is upset by application of magnetising force. From this point of view, the greater amount of surface a mass of iron present the more quickly it is likely to take up the full amount of magnetic induction proper to any applied magnetic force, and hence in laminated iron the influence of time-lag should be less conspicuous than in a solid piece. To distinguish an effect of the kind here suggested from the effect of Foucault currents is evidently difficult, since both effects depend on the metal being tested in relatively large solid masses. A possible experiment might be arranged in which a rod built up of a number of concentric cylinders should be compared with an equal rod of the same iron built up of a number of sectors parted by radial planes. Both modes of lamination would reduce whatever part of the time-lag is due to the cause just suggested, but the second mode only would be effective in preventing Foucault currents.

It is clear from the experiments of Fig. 33, and even those of Fig. 34, that ordinary ballistic tests are liable to serious error when the specimen tested is a solid bar of any considerable section, especially when the material is soft iron, unless the ballistic galvanometer has a much longer period than is usual. The need of insulation, as well as lamination, is well exemplified by the case of Ring VIII., described above.

Experiments with Groups of Pivoted Magnets.

The remainder of our experiments relate to the molecular theory of magnetic induction discussed in a former Paper by one of us.* It was there shown that, if we adopt Weber's view that the molecules of a magnetisable metal possess magnetic polarity, the phenomena of hysteresis and other prominent characteristics of the magnetising process follow as consequences of the control which the molecular magnets exert on one another by their polar forces. Thus, in the application of magnetic force to an unmagnetised piece, the molecular magnets are at first deflected stably, and in this stage there is no hysteresis. But when the force is sufficiently increased certain molecules are deflected so far as to become unstable, and a breaking up and rearrangement of molecular groups supervenes. Finally, after this process has occurred throughout the piece a third stage is entered on, when further stable deflections through a small range bring about the completely "saturated" state. Hysteresis is found whenever any of the molecules pass from one stable configuration to another through a phase of instability, and this transition, being mechanically irreversible, involves a dissipation of energy. It was shown that this conception of molecular structure gave an explanation of very many known facts regarding the magnetic quality of iron and steel, and that some of these may be effectively illustrated by means of a model consisting of a group of small magnets pivoted like compass needles on fixed centres, and placed near enough to one another to allow their mutual polar forces to be strongly felt.

In further elucidation of this theory, we have made a number of experiments with such a model. In some of them as many as 130 little magnets have been used. These were cut out of sheet steel. They were mostly lozenge-shaped, and were about an inch long and half an inch wide, but some were smaller; each had a central recess punched in it to form a socket for the supporting pivot, which was an inverted drawing-pin with a sharp point. The pins were stuck through a sheet of paper to hold them at the desired distance apart, and the paper was laid on a horizontal sheet of glass which stood between a pair of coils, through which current was passed to produce a deflecting magnetic field. Two layers of such magnets were generally used, one above the other. The aggregate magnetic moment of the group was measured by means of a mirror magnetometer, which was furnished with an adjustable compensating coil to neutralise the direct effect of the current in the two field-coils of the model.

The group having been well stirred up and allowed to settle in the absence of directing force, the current in the coils was slowly increased by means of a liquid rheostat, and galvanometer readings of it were taken, along with magnetometer readings of the aggregate moment. The numbers (with arbitrary scales) are given below, and are drawn as a curve in Fig. 35. The highest value of the current was strong enough to bring the group of magnets to a configuration approaching "saturation." It will be seen that the three stages of the magnetising process are well reproduced in the behaviour of the model, and,

* "Contributions to the Molecular Theory of Induced Magnetism," Roy. Soc. *Proc.*, Vol. XLVIII., p. 342 (June, 1890).

Digitized by Google

notwithstanding the limited number of "molecules" which took part in the operation, the readings lie fairly well on a smooth curve, which has all the general character of the curve of magnetisation in actual iron.

Current.	Moment.	Current.	Moment.
0	0	50	28
4	0	58	41
10	1	63	48
17	3	83	119
26	5	145	145
33	11	184	160
41	11	447	174

In the same way Fig. 36 shows the results obtained in carrying a group of pivoted magnets through a complete cycle, by double reversal of the directing field, after the cycle had already been gone through once or twice. Fig. 37 shows an immediately succeeding experiment on the same group, designed to illustrate the formation of small loops by the removal and reapplication of magnetic force. In these operations the behaviour of the model agrees in all respects with that of a magnetic metal.

The same close correspondence is found even in less obvious features of the magnetising process. This is illustrated in Figs. 38, 39, and 40.

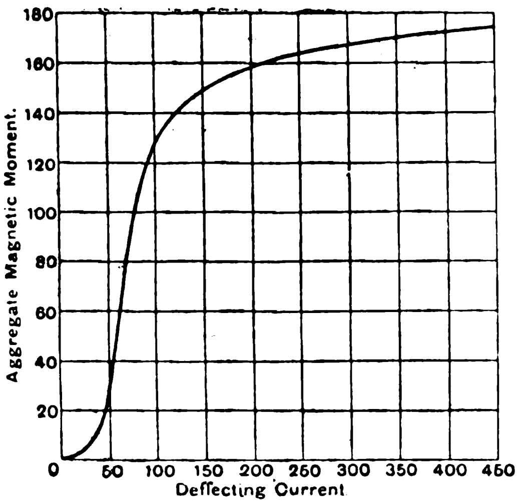

FIG. 35.—Curve showing the behaviour of a group of 130 pivoted magnets subjected to increasing directive force.

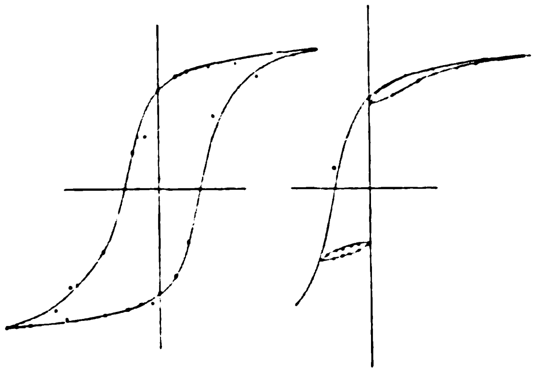
When a piece of previously unmagnetised iron or steel is acted on by a magnetic force sufficiently strong to carry the metal to the stage of high permeability, but not strong enough to make it approach saturation, and this force is then caused to vary between equal positive and negative values, it is found that the first application induces more magnetism than is induced by subsequent applications, and that the changes of magnetism do not become cyclic until the force has been several times reversed. And during this gradual approach towards a cyclic *régime* the range, through which the magnetism varies between its positive and negative extremes, becomes reduced. These effects of hysteresis are well shown by Fig. 38, which is copied from a former Paper,* and represents a test of a piece of annealed steel.

The same phenomena occur in the model, provided the little magnets have been previously shaken up and allowed to settle in the absence of any directing field: a condition which may be supposed to correspond with the annealing of the solid metal. Fig. 39 is a characteristic instance. It represents a test of the same group of pivoted magnets as was used in Figs. 36 and 37. After all effects of earlier deflecting fields had been eradicated by shaking up the group, a rather weak directing force was applied, first to the positive side, and then this was reversed three times. At the third reversal the changes of aggregate moment on the part of the group had become nearly cyclic, but with a range of variation which was decidedly less than that indicated by the first application of the field. Corresponding results were found in another experiment where the first application of the field was towards the side called negative.

* *Phil. Trans.*, 1885, Plate 61, Fig. 28. *See* also Fig. 26 on the same Plate.

Again, using a model in which there were only 36 magnets, notes were made of the position assumed by each member of the group when the directing field was (1) applied, (2) reversed, (3) re-reversed, and so on. It was seen that the configuration assumed in the first application was not reproduced in the third, nor that of the second in the fourth. But the fifth application made all the members of the group take up the same position as they took in the third, and again the sixth agreed with the fourth.



FIGS. 36 and 37.—Cyclic processes in a group of pivoted magnets.

Further, tests of iron and steel show that if we have to deal, not with a previously unmagnetised piece but with a piece on which the process of "demagnetising by reversals" has been performed, the phenomena which have just been described are not found, or, at least, are much less conspicuous than in virgin metal.

They reappear after the primitive state is reproduced by annealing. In this respect the molecular state of iron which has been demagnetised by reversals of a strong magnetic force (diminishing to zero) differs from that of a piece which has been demagnetised by annealing—or even, it may be added, by mechanical vibration.*

The same difference is found in the behaviour of the model after the two corresponding kinds of preliminary treatment. If a neutral initial state has been arrived at by a casual stirring

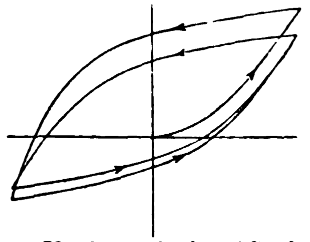


FIG. 38.—Magnetisation of Steel.

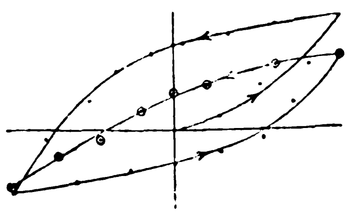

FIG. 39.—Corresponding process in Model.

up of the little magnets, the model behaves in the way shown in Fig. 38. On the other hand, if the neutral state has been produced by repeated reversals of a strong deflecting field, very slowly performed, so as not to throw the group into general agitation, and gradually reduced in range to zero while the reversals go on, the displacements of the magnets under a subsequently applied weaker field are found to fall at once into a cyclic *régime* when the field is reversed. An example of this is given in Figs. 40 and 41, which show experiments made with a group of 120 magnets. In Fig. 40 the magnets had been shaken up to begin with, and, in consequence, when the magnetic field was applied the displacements were not at once cyclic. Fig. 41 shows the behaviour of the same group under precisely the same changes of deflecting field after the process of "demagnetising by reversals" had been used to bring the group into a neutral state. Here we find a cyclic

* In illustration of this difference, reference may be made to Figs. 26 and 27 in Plate 61, *Phil. Trans.*, 1885.

régime established at once, and as near an approach to symmetry in the curve as a model with a limited number of magnets can well be expected to show. Observations made on such a model are necessarily somewhat rough, and too much stress must not be laid on particular features of the curves.

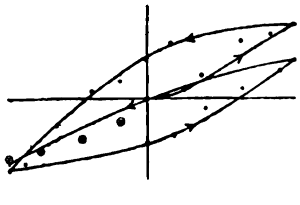

FIG. 40.

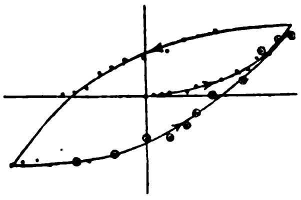

FIG. 41.

But in several repetitions of these experiments the same general distinction has always been apparent in the behaviour of the model after one and the other mode of preliminary treatment, a distinction which, as we have seen, forms a striking analogue to what is observed in actual iron or steel.

THE RELATION OF MATHEMATICS TO ENGINEERING.*

BY JOHN HOPKINSON, F.R.S.

Mathematics has been described in this room as a good servant but a bad master. It will be my duty this evening to prove by suitable illustration the first half of the proposition, and to show the service mathematics has rendered and can render to engineers and engineering.

In our Charter the Institution of Civil Engineers is defined as "A society for the general advancement of Mechanical Science, and more particularly for promoting the acquisition of that species of knowledge which constitutes the profession of a Civil Engineer, being the art of directing the great sources of power in Nature for the use and convenience of man, as the means of production and of traffic in states both for external and internal trade, as applied in the construction of roads, bridges, aqueducts, canals, river navigation and docks, for internal intercourse and exchange, and in the construction of ports, harbours, moles, breakwaters and lighthouses, and in the art of navigation by artificial power for the purposes of commerce, and in the construction and adaptation of machinery, and in the drainage of cities and towns." No better definition can, I think, be found for our profession than that it is the art of directing the great sources of power in Nature for the use and convenience of man. It covers all that the widest view of our work can include, and it excludes those applied sciences, such as medicine, which deal with organised beings. Mathematics has to deal with all questions into which measurement of relative magnitude enters, with all questions of position in space, and of accurate determination of shape. Engineering is a mathematical science in a peculiar sense. Medicine, the other great profession of applied science, has but little to do with questions of measurement of magnitudes, or of geometry; but the engineer finds them enter into everything with which he has to deal, and enter in the most diverse ways. The thing he has to determine is that the means he employs is enough and not unnecessarily more than enough to attain the end in view. For this he must necessarily numerically measure the end and the means and see that they are justly proportioned to each other. It is useless this evening to waste time proving, what all will admit, that no one can be even the humblest engineer without a knowledge of arithmetic and enough of geometry to enable him to read a drawing, that some trigonometry, some rational mechanics and a knowledge of projections, is a very useful part of the mental equipment of a draughtsman. It is hardly necessary to call attention to the great economy in the labour of calculations effected by the use of logarithms, a mathematical instrument for which we are indebted to Napier. We may with more profit examine what use the higher mathematics can be to the practical engineer, and what has been done in the past for engineering by its aid.

Judging from etymology, mathematics must have been begun by engineers; for surely geometry is the work of the earth measurer or land surveyor. But since the prehistoric times when geometry was initiated, engineers have not added much that is new to mathematics. They have rather sought amidst the stores of the mathematician and selected the handiest mathematical tool they could find for the particular purpose of the moment, but have done little or nothing in return in the way of improving the tools which they borrow. In this respect the relation of engineering to mathematics differs much from its relation to experimental physics. In electricity, magnetism, and heat, engineers have from their practical experience repeatedly corrected the ideas of the theorists, and have started the science on more accurate lines. If our subject to-night had been the use of the practical applied science of engineering in promoting the development of pure mathematics, we should speedily find that there was hardly any material for discussion. The account being all on one side, let us see to what the debt of the engineer to the mathematician amounts.

There is no department of practical engineering in which the application of mathematics is more familiar than in that which relates to the calculation of the strength and rigidity of structures of various kinds. It is impossible to take up any book dealing with the subject without finding that it is crammed either with mathematical formulæ, or with geometrical figures. The question is not whether mathematics is necessary to an adequate comprehension of the subject, but whether analytical or purely geometrical methods are more convenient. Of course, one might occupy many lectures in discussing the practical application of mathematics to the question of bridge building, roofs, guns, shafting, and the like. Our object must be to illustrate by various examples rather than to attempt anything like a complete discussion.

Consider the case of a long strut, so long that its transverse dimensions can be regarded as insignificant in comparison with its length. Whilst the strut remains perfectly symmetrical about its middle line, its strength will depend only upon the resistance of the material to crushing. Everyone knows that this would be an inadequate conclusion; we have to consider another element, namely, its stability, that is, we must examine what will happen to the strut if from any cause it is displaced somewhat from the direct line between its extremities. A mathematical discussion of the question results in a differential equation of the second order with one independent variable. Upon consideration of this we are enabled to see that if the thrust upon the strut be less than a certain critical value, a slightly bent strut will tend to return to its straight condition; but that if the thrust upon the strut be greater than this critical value, the displacement will tend to increase, and the strut will give way. Further, that the critical value will depend upon whether one or both of the two extremities of the strut are held free, or whether they are rigidly attached by flanges or otherwise, so that the direction of the axis of the strut at this point must remain unaltered. Again, we infer that if the ends are held rigidly fixed, the length of the strut may be twice as great for a given critical value of the thrust as if the two ends are free to turn. We can also infer what the critical value will be for struts of various lengths and of varying cross-sections. This critical value depends not upon the resistance of the material to crushing, but upon its rigidity.

Another example, having a certain degree of similarity with the case of struts, is that of a shaft running at a high number of revolutions per minute, and with a substantial distance between its bearings; for simplicity, we will suppose that there are no additional weights, such as pulleys, upon the shaft. How will the shaft behave itself in regard to centrifugal force as the speed increases? In this case, so long as the shaft remains absolutely straight it will not tend to be in any way affected by the centrifugal force, but suppose the shaft becomes slightly bent, it is obvious to anyone that if the speed be enormously high this bending will increase, and go on increasing until the shaft breaks. In this case also we may use mathematical treatment; we find that the condition of the shaft is expressed by a differential equation of fourth order, and from consideration of the solution of this equation we can say that if the speed of any particular shaft be less than a certain critical speed, the shaft will tend to straighten itself if it be momentarily bent, but that, on the other hand, if the speed exceeds this critical value, the bending will tend to increase with the probable destruction of the shaft. I do not know that either of these two questions can be properly understood without some knowledge of differential equations.

A problem having a certain analogy to those to which I have just referred is that of hollow cylinders under compression from without, such as boiler tubes. Whether the tubes be thick or thin, so long as they are perfect circular cylinders, they should stand until the material was crushed. But if the tubes are thin, what will happen if the tube from any cause deviate ever so little from the cylindrical form? The solution cannot be obtained without a substantial quantity of mathematics.

The next illustration shows how a mathematical conclusion, correct within the limits to which it applies, may mislead if applied beyond those limits, and how a more thorough mathematical discussion will give a correct result. Considering a case of shafting in torsion, it was show by Coulomb that the stiffness and strength of a shaft having the form of a complete circular cylinder could be

* The "James Forrest" Lecture, delivered before the Institution of Civil Engineers, May 3rd,

Digitized by Google

readily calculated if the transverse elasticity of the material and its resistance to shearing were known. From the complete symmetry about the axis it is evident that points which lie in a plane perpendicular to the axis before twisting will still be in that plane when the shaft is twisted; it is also clear that the angle through which all points in the same plane move will be the same; hence the problem was as simple as problem could be. But many who had occasion to make use of Coulomb's results gave them an application which was wholly unwarranted. They assumed that they were equally applicable to other cases than complete circular cylinders; they assumed, in fact, that every point of the material which lay in a plane perpendicular to the axis would remain in that plane when the shaft was twisted, whether the shaft was symmetrical about its axis or not, and they consequently arrived at very erroneous results. That the assumption was erroneous is obvious enough from a consideration of an extreme case. In Fig. 1 is shown in cross-section a hollow cylindrical shaft, which is not complete, but divided by a plane passing through its axis. In this case the shaft when twisted will be as illustrated in the side elevation; two points, A and B, were in one plane perpendicular to the axis when the shaft was free from twist; they cease to be in one plane when the shaft is twisted. St. Venant* in 1855 investigated the questions of shafts without making incorrect assumptions; he expressed the condition of the material by a partial differential equation of the second order, and gave suitable surface conditions. A general solution of the problem for all forms of shafts has not been obtained, but St. Venant gives a number of solutions for particular forms, and he obtains some general results of interest. In all cases the stiffness of the shaft is less than would be inferred from an erroneous application of Coulomb's theory. Fig. 2 shows diagramatically the strain in a shaft of triangular section; the full lines indicate that the parts of the shaft which lay in one plane before twisting when twisted rise above the plane; the dotted

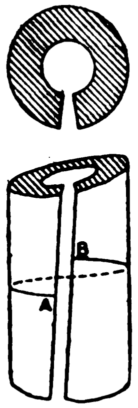

FIG. 1.

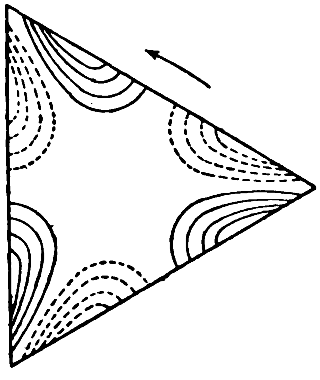

FIG. 2.

lines indicate that they lie behind the plane of the paper. The shearing stress is least at the angles of the triangle, and is greatest at the middle of the sides. At this point, then, the shaft will begin to break under torsion. The fact is probably well known to men of practical experience, but it is directly contradictory to the conclusion at which one would arrive by a careless use of Coulomb's theory beyond the narrow limits within which it is applicable. The longitudinal ribs which one often sees on old cast-iron shafts are useful enough to give stiffness to the shafts against bending, but are good for very little if torsional stiffness or torsional strength is desired.

Another application of mathematical theory which has been carried somewhat further than the premises warrant is found in the case of girders. It is almost invariably customary to treat a girder as though the sections retain when the girder is bent the form and size which they had before bending. Making this assumption, it is very easy to calculate the strength and stiffness of a girder of any section. Unfortunately, the assumption is untrue; but, fortunately, it is approximately true in the case of most girders with which engineers in practice have to deal. That it is untrue can be readily seen from consideration of a girder of exaggerated form, the section of which is shown in Fig. 3. Any practical man would at once see that the outer parts of the flanges would add little to the strength of the girder, but according to the usual mathematical theory, the outer parts of this flange should be as useful as the parts which are nearer to the webb. This problem St. Venant also deals with in a rigid mathematical manner. Amongst other things, he showed that a girder of rectangular section, such as shown in Fig. 4, would, when bent, take the form shown by the curved lines in the same Fig. The last two examples show how a little knowledge may be a dangerous thing, and how easy it is for anyone who attempts to apply mathematics without adequate mathematical knowledge to be misled.

The theory of thick cylinders under bursting stress from within has many important practical applications to hydraulic presses and to guns. It has been discussed more than once in this room. As usual, in considering these cases, we are immediately led to differential equations, which here are fortunately solved without serious difficulty, and the solution tells us the whole story. We learn that doubling the thickness by no means doubles the strength of the cylinder. And as a converse, that doubling the strength of the material will permit the thickness to be diminished to much less than one-half. Twenty-five years ago hydraulic presses were mostly made of cast-iron. Many people were not a little astonished at the great reduction in thickness and weight which became possible when steel was substituted for the weaker material. In the case of guns it is well known that greater strength can be obtained if the outer hoops are shrunk on to the inner ones.* Mathematical theory tells us what amount of shrinkage should give the best results. It may possibly not be worth while to follow the results of theory precisely, but without the guidance of theory it would not be unnatural to give so great a shrinkage that the gun would be weaker than if no shrinkage were used.

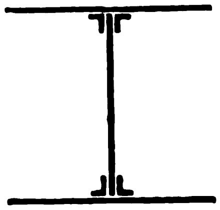

FIG. 3.

The rolling of ships in a seaway gives an illustration of a principle which has very varied application in many branches of physics. Suppose a body is capable of oscillating in a certain periodic time, and that it is submitted to a disturbing force of given period, the equation of motion easily shows that the resulting disturbance will be great if the two periods are equal or nearly equal. We meet with the principle in acoustics as resonance. If two tuning forks are tuned to the same pitch, and one is sounded in the neighbourhood of the other, that other will presently be thrown into vibration by the waves transmitted through the air from the first. You may try a similar experiment at any time on any piano. Strike the higher G in the treble, the sound ceases on raising the finger. Now hold down the middle C, and again strike G; the C string at once takes up the note sounded, and can be heard after the exciting string has been silenced by damping. The same fundamental idea is found in the lunar theory in the term in the equation known as the evection, and again in the theory of Jupiter's satellites. The reason why the metals present in the solar atmosphere give black lines in the spectrum by absorption, corresponding in position with the bright lines in the spectrum which the same metals give when incandescent, is again the same. Gas will absorb or take in from the ether waves of the exact period which it is capable of giving to the ether. The general explanation of all these phenomena is easy. Imagine a pendulum, and, suppose it experiences a periodic disturbing force, the first impulse of the disturbing force gives the pendulum a slight swing, the effect of the second impulse depends entirely on when it occurs, it may occur so as to neutralise the effect of the first, or it may occur so as to increase it. If the period of the force is the same as the natural period of the pendulum, the effect of the second, third, and later impulses will be added to the effect of the first, and the final disturbance will be great, even though the individual impulses be minute. But the mathematical theory tells us much more than any general explanation can do. It tells

Digitized by Google

us exactly what the character of the effect will be, and its amount if the periods are nearly but not exactly the same. It tells us, too, exactly how friction affects the results. And the beauty of it is that the mathematical theory is much the same in all cases, so that having learned to deal with one case we are enlightened as to a host of others. The oscillating body may be an ironclad, or it may be an atom of hydrogen, the disturbing periodic force may be the waves of the Atlantic, or it may be the waves in the ether occurring five hundred millions of millions of times in a second; it is all one to the mathematician, the treatment is substantially the same.

The question of the speed of ships and the power to propel them is probably more effectually treated by experiment on models, as was done by the late Mr. Froude, than by mathematics alone; but in order to learn from the experiments all they are capable of teaching a mathematical understanding is needed. Given that we know by experiment all about a given model, that we know what force is needed to propel it at every speed, we want to know from these experiments how a great ship, 100 times as big, but similar in form in every respect, will behave, and here mathematics come in to aid us in making the inference.

The construction of ships at once leads us on to the methods of navigating them. In navigation I should find much material for my purpose, but navigation is not usually included in engineering, but many of the implements of navigation undoubtedly are. The mariners' compass has for ages been the mainstay of the navigator, and a simple enough instrument it was till it was disturbed by the iron of which ships came to be built. The disturbance of the compass by the iron of the ship was first seriously attacked by two senior wranglers, Sir G. Airy and Mr. Archibald Smith. The disturbance may be divided into two parts, the first due to the permanent magnetism of the ship, the second to the temporary magnetism induced by the earth's inductive action on the iron of of the ship—the first causes the semicircular, the second the quadrantal, error. One has only to open the "Admiralty Manual of Deviations of the Compass" to see how the mathematics of Archibald Smith have accomplished a proper understanding of the subject. The errors of the compass are dealt with in two ways: they are compensated by soft iron correctors, and by permanent magnets so placed as to have an effect equal and opposite to the effect of the temporary and permanent magnetism of the ship. Or they are dealt with by formulæ of correction which enable the error to be calculated when the course of the ship and the conditions of the earth's magnetism are given, or a combination of the two methods is used. Either method is based on Archibald Smith's theory. It is not possible to leave the subject of the mariners' compass without referring to the great improvements of Lord Kelvin. The improvements relate to every part of the instrument, and I venture to say that none of them could have been made by any one but a mathematician. In order to get his card steady he knew that its period must be different to any possible period of the waves, or he would have the resonance to which I have just referred coming in, so he gave his card a considerable moment of inertia; but this was managed with a light card, so that small needles could be used. If the needles are small the correction by soft iron masses and by permanent magnets is easier and more accurate. Then the bowl of the compass had to be suitably carried, so that it would not be unduly disturbed by shock, and provision had to be made for damping by fluid friction the oscillations of the bowl if they occurred. Lastly, a most beautiful method of correcting the compass, without taking a sight, was discovered. In every detailed improvement one can detect that the inventing mind was that of a most able and trained mathematician.

An essential of safe navigation is an efficient system of lighthouses. The optical problem of the lighthouse engineer is to construct apparatus which shall usefully direct all the light produced. The present forms of apparatus are in their leading features due to Fresnel, the able mathematician, who established on an absolutely firm foundation the undulatory theory of light. To properly design an optical apparatus formulæ must be used, and the advantage is great if the designer can with ease manufacture the formulæ he requires.

(To be concluded.)

ELECTRIC MINING MACHINERY.

Considering the protracted stoppage of the collieries last year, in the fruitless endeavour of the coalowners to enforce some reduction in wages, and the attitude taken by the Miners' Federation on the question of fixing a minimum rate of wage, which seems likely to result in further troublous times for the coal trade in the very near future, it would certainly seem strange, says a correspondent of the *Engineer*, that not more attention has been directed by colliery owners to the introduction of mechanical appliances for the getting of coal, not only as a question of economical production, but with a view of helping them out of the serious difficulties they have to encounter with the men. This question was raised in a Paper recently read before the Manchester Geological Society by Mr. Joseph Crankshaw, who described a pneumatic-electric coal-cutting machine, patented by Mr. Hurd, which is an improvement upon a similar machine which he introduced many years ago. The reader, in the course of his Paper, said that not only for the sake of economy, but in the cause of humanity, it was a reflection on the enterprise of Lancashire that there was not a single coal-cutting machine at work to-day in the Manchester district. In the discussion which followed upon the reading of the Paper, Mr. Hurd, the inventor of the machine, remarked that although they had numerous inquiries from abroad, and from such long distances as India and China, the home demand for these machines was practically *nil*. This, he thought, was an extraordinary state of things, as the saving to be effected by such mechanical appliances in the getting of coal was incredible. He had no hesitation in saying that by the use of these machines they could effect a saving of from 1s. to 3s. per ton on the total cost of production, according to circumstances. Mr. W. Saint, Government Inspector of Mines, the president of the Society, remarked that the machine seemed to be adapted more particularly for a long wall, whilst in Lancashire the system of working was mostly pillar and stall. Mr. Cockson remarked that the reason why coal-cutting machines had not been more largely adopted in the collieries throughout Lancashire was not that there was any prejudice against them, or unwillingness on the part of the coalowners to adopt mechanical appliances, but simply because the inventive engineers had not produced machines to work successfully with the bad roofs they had in most of the mines. Mr. Hurd replied that these machines were especially adapted for bad roofs, owing to the speed with which they got through the work, as compared with hand labour, which rendered the risk of roof falls very much less. Mr. Dickenson referred to a coal-cutting machine working successfully in the Normanton district, which had enabled the proprietors of the colliery to effect a saving in the getting of coal of fully 6d. per ton. It was strange, he added, that Lancashire should be so deficient in coal-cutting machines; they had, however, been tried in different collieries, but had been given up. Mr. W. Saint, in closing the discussion, agreed with Mr. Hurd that the rapidity with which the cutting was done by this machine might greatly tend to lessen the risk of falls of roof, and their introduction might be the means of preventing a large number of accidents which at present occurred in working places from this cause.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

TO-DAY) FRIDAY, May 11th.

PHYSICAL SOCIETY.

5 p.m. The following Papers will be read:—(1) "Electromagnetic Induction in Plane Cylindrical and Spherical Current Sheets," by G. H. Bryan, M.A. (2) "Dielectrics," by R. Appleyard.

SATURDAY, May 12th.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture: "Colour Vision," by Capt. Abney, F.R.S.

TUESDAY, May 15th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Rubies: their Nature, Origin, and Metamorphoses," by Prof. J. W. Judd, F.R.S.

WEDNESDAY, May 16th.

ROYAL METEOROLOGICAL SOCIETY.

8 p.m. Ordinary Meeting at 25, Great George-street.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Ordinary Meeting at 20, Hanover-square, W.

THURSDAY, May 17th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Solid and Liquid States of Matter," by Prof. Dewar, F.R.S.

FRIDAY, May 18th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 28, Victoria-street. The following Paper will be read:—"Notes on Gas-Engines," by P. W. Paget.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Splash of a Drop and allied Phenomena," by Prof. A. M. Worthington, F.R.S.

SATURDAY, May 19th.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture: "Colour Vision," by Capt. Abney, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

(The Oldest Electrical Journal, 1861–1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing, and Printing Offices:

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

'THE ELECTRICIAN' *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months. s. d.	6 months. s. d.	12 months. s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as* an *Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
- VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
- VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d. post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free. Also in German, 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

In Preparation. Very fully illustrated.

ELECTRIC LAMPS AND ELECTRIC LIGHTING.

Being Four Lectures delivered in April-May, 1894, before the Royal Institution, by Prof. J. A. FLEMING, M.A., D.Sc., F.R.S.

SPECIAL NOTICE.

Last week's number of "THE ELECTRICIAN" commenced Vol. XXXIII. and contained (Gratis) the Index to Volume XXXII.

NOW READY.

Volume XXXII. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad, carriage extra.

Cases for binding Volume XXXII., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

THE RELATION OF CAMBRIDGE MATHEMATICS TO ENGINEERING.

The "James Forrest" lecture, the first portion of which is printed in our present issue, is worthy alike of the occasion, of the subject, and of the author. In venturing, however, to criticise, and even to disagree with parts of this Address, we say once for all, lest our remarks may be misunderstood, that we neither underrate the value of mathematics nor the acquirements of Dr. HOPKINSON. Dr. HOPKINSON treats, not of mathematics, but as we have indicated in the title of this article—of Cambridge mathematics. Many times in these columns have we pleaded for the development of geometry and of graphics, and have commented on misplaced algebraical work; but we have never before had occasion to distinctly protest against the assumption that one branch of mathematics is of supreme importance. In the fourth paragraph of the Address a more liberal view is suggested, but it is not followed up, and the question it asks is not answered. "The question is not whether mathematics is necessary to an adequate comprehension of the subject, but whether analytical or purely geometrical methods are more convenient." The expression "analytical" is sometimes used for algebraical as distinguished from geometrical mathematics; whether it is so used here or no is not quite clear. In the last paragraph but three of the Address, "analytical" is used in an entirely different sense, and we shall therefore adopt the expression "algebraical" on the present occasion. The school of mathematics of which Dr. HOPKINSON is a representative

Digitized by Google

is by no means to be despised. Pure science and much applied science would be at a standstill without it. The idea of Lord RAYLEIGH lecturing before the Royal Society on the relation of algebraical mathematics to physical science is all but ridiculous. The two things are nearly identical from the point of view of that distinguished physicist. The mere fact that MAXWELL in 1869 gave to engineers the graphic stress diagram for girders and appended certain diagrams to the end of his "Electricity and Magnetism," is almost sufficient to exclude him from the Cambridge School of mathematicians. This is the sort of mathematics which engineers can thoroughly appreciate and profitably use. Had MAXWELL lived, we do not doubt but that he would have bestowed other similar gifts; but Cambridge has not lifted a finger in this direction. Cambridge mathematics is the result of a vicious circle to which we have alluded on a previous occasion: school-boy, scholarship, wrangler, school-master. Another smaller circle, whose viciousness is inversely as its diameter, touches this wide one, and is: examinee wrangler, examiner. Few schoolmasters care to teach that which will not "pay" at the Universities, and where mathematics is concerned, the question is, what will pay at Cambridge? It is possible, however, that the question does not even arise, if the schoolmaster is a Cambridge man, and knows nothing and cares for nothing but the high and dry pure mathematics that he read at Cambridge. At Oxford, thanks mainly to the influence of that eminent geometrician, the late Prof. HENRY J. SMITH, graphics are better appreciated, and the great work of LUDOVICI CREMONA is duly recognised.

The first examples given by Dr. HOPKINSON are the strength and stability of struts and of revolving shafts, and he concludes "I do not know that either of these two question can be properly understood without some knowledge of differential equations." We are very sorry that this is so; it ought not to be the case. After alluding to one or two cases in which ST. VENANT pushed COULOMB's theory further than was admitted by the conditions, Dr. HOPKINSON confesses that "any practical man would at once see that the outer parts of the flanges would add little to the strength of the girder, but according to the usual mathematical theory, &c., &c. . . . This problem ST. VENANT also deals with in a rigid mathematical manner." We are not going to sing the praises of the practical man, still less to decry mathematics, nor even to blame ST. VENANT, but we quite agree with Dr. HOPKINSON that it is easy for anyone who attempts to apply mathematics without adequate mathematical knowledge to be misled; and this, we venture to think, is largely due to the liability of certain kinds of mathematics to mislead. With reference to harmonic vibrations, he says, "The mathematical theory tells us much more than any general explanation can do . . . and the beauty of it is that the mathematical theory is much the same in all cases, so that having learned to deal with one case, we are enlightened as to a host of others, ... it is all one to the mathematician, the treatment is substantially the same." Higher mathematics, indeed, deserves its name on this account, but we maintain that geometry, even in its present undeveloped state, has some claims to general application. That very FOURIER's theorem which Dr. HOPKINSON contemplates above as the key to harmonic vibrations, and much beside, can be set forth perfectly by graphic construction. Nay, the whole existence of that exquisite machine, the harmonic analyser, which will enable an ordinary skilled draughtsman to solve, in a few minutes, problems which not even Dr. HOPKINSON could without it solve in as many hours, is based on geometric properties, not on their merely algebraic expression. It is not too much to say that he who has learned FOURIER's theorem, from its mere algebraic representation as a trigonometrical series, without regard to its true geometrical significance, has not even begun to understand its real essence. Clock-face diagrams in alternate-current work, and Zeuner diagrams in steam-engine work, are examples of very valuable applications of pure geometrical mathematics to problems which become highly complicated if translated into algebraical language. We believe that both of these diagrams have a high degree of generality, to use a favourite mathematical phrase. "It is not possible," says Dr. HOPKINSON, "to leave the subject of the mariner's compass, without referring to the great improvements of Lord KELVIN. The improvements relate to every part of the instrument, and I venture to say that none of them could have been made by anyone but a mathematician. . . . . In every detailed improvement one can detect that the inventing mind was that of a most able and trained mathematician." Here we have to differ entirely from Dr. HOPKINSON: if we may be allowed without offence to say so, we venture to say that this statement could not have been made by anyone but a mathematician. We should say, on the other hand, that one can detect that the inventing was that of a good seaman and competent navigator, an experienced instrument maker, a practical electrician, a man of mechanical instincts, and indeed an engineer, for Lord KELVIN is all this and more. Indeed, it is notorious that when, less than two years ago, Lord KELVIN brought an action against a Liverpool compass-maker for an alleged infringement, the defence which the Court held proved was that Lord KELVIN's improvement had been anticipated. And the anticipator was not a trained mathematician at all! We should be sorry to undertake a voyage in a vessel equipped only with a compass designed by a mathematician.

Passing to lighthouses, we learn "to properly design an optical apparatus, formulæ must be used." We again venture to disagree entirely. The data of this problem are certain angles and a refractive index. No very high degree of accuracy, as in a trigonometrical survey is useful, because the source of light is far from being a point. The required result is a drawing or a set of templates. Any such problem can be safely and expeditiously solved by pure geometry, either by graphic methods or with the assistance of suitable mechanism. Where drawing pen and drawing paper fail, needle and sheet metal, almost unknown owing to the undeveloped state of graphics, may be used. In Dr. HOPKINSON's next example he is good enough to resort to a diagram showing, as indeed nothing else can show it, the propagation of an electric disturbance in a submarine cable, or the transmission of heat through a plate. A portentous formula accompanies this example, and Dr. HOPKINSON dismisses the subject with:—"Here again it is difficult to see how the differential equation and its solution can be evaded." Here again we differ diametrically; and unhesitatingly assert that this result can be obtained by a tolerably simple geometrical construction. We have never seen it, we do not know that it has been done, but we have seen something resembling it sufficiently closely to say that Dr. HOPKINSON is welcome to the formula, that all praise is due to Lord KELVIN who solved the equation, but that a graphic construction will suffice well within the limit of practical measurement and observation. Of course, the graphic construction will not tell the mathematician or the physicist so much as a formula; but we are concerned here with a definite piece of design; the engineer, as an engineer, has no time for mathematical or physical investigations into scientific side questions. No hard-and-fast line can be drawn between problems which are

Digitized by Google

suitable for geometrical treatment and those which can only be attacked by algebra. That by which the desired result can be most cheaply attained is the best one for the engineer. In estimating the cost of a calculation, not only the time but the value of the calculator as a tool must be considered. It may be cheaper to employ a draughtsman for three hours than a wrangler for three minutes. MAXWELL did not suggest that stress diagrams should altogether supersede the older methods of calculation. "In calculating the stresses of frames," he wrote in the Paper to which we have referred, "the graphic method is really useful, and is less liable to accidental errors than the trigonometrical calculation. In cases of continuous stress, however, the symbolical method of calculation is still the best, although, as I have endeavoured to show in this Paper, analytical methods may be explained, illustrated, and extended by considerations derived from the graphic method."

Dr. HOPKINSON's examples serve to weaken the case which he might have made out had he kept to generalities, and had he left his hearers in some doubt as to the kind of mathematics to which he was referring. The value of mathematical research to engineering science cannot be over-estimated, but this is not the theme of the lecture. It treats of mathematics as the good but not always faithful servant of the engineer. So far is geometry behind algebra to-day, that it is difficult to say that the former will ever become so powerful and general a branch of mathematics. Its present condition in this country is largely due to the neglect, and we would even say, the ignorance of geometry at Cambridge. Two or three men have written on graphic methods, chiefly of an apparently special character. Their generality will lie unsuspected, but we are convinced that it exists. "Engineers," says Dr. HOPKINSON, "have not added much that was new to mathematics." Dr. HOPKINSON himself, as an engineer, rather than a mathematician, gave us that invaluable diagram, which MARCEL DEPREZ afterwards called a "characteristic curve." Let the honour of this discovery atone for all the shortcomings which we have attributed to the Cambridge school of mathematics in its relation to engineering.

THE ELECTROLYSIS OF FUSED SALTS.

Mr. Claude Vautin read a Paper on this subject before the London Section of the Society of Chemical Industry on Monday last. The essential point of the processes which the author described is that a cathode of some heavy metal, *e.g.*, lead or tin, is used in a bath of the salt (generally a chloride) to be electrolysed. Thus, tin may be employed as the cathode in a vessel filled with fused potassium chloride, or lead in one containing sodium chloride. The course of the reaction caused by electrolysis is the same in all cases. The metal whose chloride is electrolysed appears at the fused metallic cathode, and forms an alloy, while the chlorine is given off at the anode (of retort carbon) dipping in the fused salt. In this way potassium-tin and sodium-lead can be readily prepared. The latter is, of course, of most commercial importance, as on its production a practicable process for the electrolytic manufacture of caustic soda and bleaching powder is based, the method being thereby put at once into rivalry with such wet processes for the decomposition of sodium chloride as are now being tentatively worked. The question of the best form of apparatus is not yet settled, though a trial plant is being erected near Manchester; but in all cases the type of apparatus will consist of a basic-lined electrolytic pot, covered to collect chlorine and externally fired to keep the salt in a state of fusion, and a decomposing vessel into which the sodium lead is run and treated with water or steam for the production of caustic soda. However the apparatus may differ, the reactions involved are identical, being given by the equations—

$$NaCl = Na + Cl,$$

the sodium being absorbed by the fused lead cathode; and,

$$Na + H_2O = NaOH + H,$$

caustic soda being produced and hydrogen given off. The function of the fused lead cathode is to collect and retain the sodium which would otherwise float upon the surface of the bath and volatilise or unite with the chlorine. The sodium-lead alloy, which is formed at the cathode, is a curious material, being remarkably brittle and oxidising with great rapidity. A clean fractured surface tarnishes immediately on exposure to air. The alloy can be prepared of various degrees of richness in sodium, its ease of oxidation naturally increasing with its content of the alkali metal. It can be kept under petroleum, but decomposes water with a speed dependent upon its content of sodium, the richer alloys reacting with almost explosive violence. The lead is not affected by this reaction, but is set free in a loose, spongy form, none, it is stated, going into solution. By regulating the admission of steam to the surface of the fused alloy, as it is proposed to do in the process of manufacture, no water in excess of that needed to form caustic soda need be used, and the fused caustic can be drawn direct off the surface of the fused lead (thus freed from sodium) in a marketable condition. The evaporation necessary for recovering caustic soda from electrolysed brine is therefore done away with and a saving effected. The absence of a diaphragm and the low resistance of the electrolyte also give the process tangible advantages over wet methods. The efficiency claimed as deduced from experiments recently made is 80 per cent., but no estimate of manufacturing cost has yet been given. Data on this most important point will be, presumably, forthcoming when the trial plant alluded to above is at work.

A high current density up to several hundred amperes per square foot can be adopted, and the minimum voltage at which the decomposition can be conducted is stated to be a little under two volts. In the discussion which followed the reading of the Paper, the upholders of wet processes for the electrolytic decomposition of common salt claimed an efficiency as high as 85 per cent., and insisted on the additional cost incurred by the need for salt in the solid form for the dry process in place of brine for the wet. Doubt was expressed as to the perfect freedom from lead of the caustic soda produced, a point of some moment. The conclusion was arrived at that whatever the relative merits of wet and dry electrolytic methods for the manufacture of alkali and bleach, the very worst electrolytic method was intrinsically farther in advance of the chemical processes at present in use than was any given electrolytic process better than its rivals of the same kind.

COST OF ELECTRICAL ENERGY.*

BY R. E. CROMPTON, M.INST.C.E., VICE-PRESIDENT.

(Concluded from page 11.)

When speaking of the differences which exist between the calculated consumption of fuel and water by the plant when tested under full load and that which is observed from the water and coal bills in the month's or year's working, I was at one time doubtful whether any single 24-hour test would include within it the observed losses; but during the past year, having made a large number of such 24-hour tests at our Chelmsford works, I have come to the conclusion that such 24-hour tests which follow a complete cycle of the working are a fairly trustworthy guide to the annual losses; and I cannot too highly recommend the practice of taking such tests, and of showing them graphically in the manner universally adopted by mechanical engineers, and shown by Prof. Kennedy in the discussion which followed on my Paper in 1891. Diagram VII. shows the way in which we plot a 24-hour test at Chelmsford, and this may be applied to any other works. Many of you will ask how I have been able to obtain the electrical work at the terminals of the dynamo in the case of the Chelmsford works, where we use alternating dynamos. My answer is, that it is only during the last few months that I have been able to do this; and it is owing to the extreme kindness

* Paper read before the Institution of Electrical Engineers, April 26th.

Digitized by Google

of Prof. Fleming, and his unwearied attention in perfecting the Mengarini wattmeter for our purpose, that we have been able to obtain a daily record of the electrical energy generated by our alternating plant, as well as that generated by our direct plant. Diagram VIII. shows an enlarged diagram obtained from this wattmeter, and we have divided it up into known portions of the load from cards taken on other nights. We are able to separate the load in the town shops from the load in private houses owing to the fact that it is the custom at Chelmsford on Wednesday night to close all the shops, so that our load on that night consists entirely of the public lighting, which is an ascertained and invariable quantity, on which is superposed the lighting in the private houses only.

It will be interesting to many here to know that the circumstances under which we work at Chelmsford of supplying the light between certain hours has enabled us to greatly cut down the transformer loss, so that we have been able to show an efficiency of distribution reaching 76 per cent., which I believe is probably as high as has ever been reached with alternating plant; but if we were compelled to keep the supply up through the remainder of the 24 hours, I am afraid the state of affairs would be widely different. We are also aided by such a large part of our load being public lighting, which goes on throughout the entire hours of darkness in summer and in winter.

Fuel and Water.—Part III.

Effects of Distribution Efficiency.

I am obliged to introduce this question into this Paper, as there can be no doubt that the high consumption of fuel shown by certain works is partly due to low-distribution efficiency; but I do not propose to dwell on this highly important question, which merits a Paper to itself, besides being of a highly controversial character. I find that in few cases have the engineers of supply works had the pluck to face this important problem, and to ascertain and state boldly what distribution efficiency they have noted. In several cases, however, this has been done, so that I am able to make the Table VI. reasonably complete. From it you will see that the efficiency of distribution of direct systems, including meter losses, varies between 85 and 91½ per cent., whereas that of converted systems varies between 60 and 82 per cent.; the higher figure being only found where the system of switching transformers in and out of circuit is practised. In the very small loss of from 10 to 12 per cent. observed in the direct systems are included all those due to the accumulators, to the C^2R losses in the mains, to leakage, and to meters failing to register; and I do not think it is likely in the future we shall be able to improve much, if at all, on this distribution efficiency—in fact, we are assured by our American friends that it would pay us better to somewhat reduce this efficiency by putting less copper in our mains; but we consider that our English practice is right, as in order to get thoroughly steady lighting and good regulation it is necessary to work at this high efficiency, and at the present price of copper it can be easily shown that it pays to do so.

Stores, Water, Labour, and Superintendence.

Under the head of "Stores used in the Generating Works" are usually included water (which in London and many other towns has to be paid for), oil, grease, waste, packing, gauge glasses, and other materials which are from day to day used in the working of a supply works. The decrease in the stores item in several of the companies has been very noticeable during the last few years of working. In the case of the Kensington Court works of the Kensington Company, the stores have in some months reached as low a figure as 0·025d. per unit sold, and there is no doubt that even a lower figure will be reached as the output and load-factor improve. In this question of use of stores, the closed type of engine, such as those made by Messrs. Willans, Bumsted and Chandler, and Belliss, of Birmingham, compare most favourably with the open type of engines. During a visit paid to Vienna, two years ago, I was told by Mr. Melhuish, the engineer in charge of the Imperial Continental Gas Association, that the consumption of oil by an open-type compound engine which they had recently erected in that station was 16 times as great as the consumption of oil by a Willans engine of equal power, and I think that in many cases differences almost as great as this will be observed between the two types of engines. When it is considered that in the close type the only glands there are to pack are those of the governor gland and at the two ends of the crank shaft, whereas in a compound or triple open-type engine there are certainly not less than eight important glands to pack, and not less than 20 oiling points requiring separate attention, it will be seen how great the difference is. In the case of rope-driving sets there are in most cases three dynamo bearings to be oiled instead of the one bearing in the case of the direct-driven set, and the side strain on the bearings necessitates nearly a fivefold use of oil.

Table VII. gives the cost of stores in the same works as Table III., from which it will be seen that, whereas some of the works using direct-driven plant have already come within a measurable distance of the figure of 0·03 for water and petty stores, those using belt, or rope-driven sets are a very long way from it.

Ideal works	N to Q, S to W	0·03	0·2	

Items 4 and 5, Wages and Superintendence in Works.

On Table VII. I also give these two items for all of the works, showing a somewhat slow progress towards my ideal figure of 0·2d. per unit. This table shows that the lowest figure yet reached is 0·38d. per unit; but, as this figure is very largely a question of output, it is certain that from the increase of output alone, and without the introduction of any refinements having for their object the reduction of the staff employed in the stations, the wages and superintendence charge may be easily brought down. It is evident, however, that this charge must be much higher in the case of belt or rope-driven machinery than is the case with direct driving, and Table VII. shows this to a very marked extent. There is every reason to believe that with direct-driving closed-type engines 1,000 kilowatts will demand the services of only one attendant, whereas it is doubtful whether with rope or belt-driven and open engines one man could attend properly to more than 600 kilowatts of plant. This, however, it only my opinion, as in neither case has the output of any existing works been sufficiently large to enable the attendants to have their time occupied in the most profitable manner; it is quite certain, however, that under present conditions the use of accumulator storage has a most important effect on reducing the cost of attendance. Whether this will be so in the future, when the all-night loads begin to be heavy, I am at present not able to say, but I hold a very strong opinion that a proper proportion of accumulator storage will even in large stations reduce the cost of attendance at least 30 per cent., and in smaller stations from 40 to 50 per cent.

Maintenance.

I have considered this part of the subject with considerable care. It is the one point on which existing opinions vary through very wide limits, and, as far as I can judge, opinions incline at present in what I believe to be an unsafe direction; that is to say, too much has been made of the extremely light cost of repairs of existing works during the few years that they have been running, and figures have been founded on this which I am afraid will turn out to be altogether illusory. In all other businesses the upkeep of boilers which require to be periodically fired up and cooled down, and which have to be heavily fired at times of maximum load, is put down at a figure varying from 5 to 10 per cent. on the original cost of the boilers. The upkeep of steam-engines

Digitized by Google

when worked at a far easier rate than is usual in electric supply works is usually taken at from 3 to 5 per cent. on their first cost; whereas the published accounts show that nothing like these figures have hitherto been spent on, or put aside for, the maintenance of these parts of the plant. I do not think that any accurate estimates can be formed of the ultimate cost of maintaining electric generating and distributing plant, other than on a percentage basis such as I have introduced in both my previous Papers.

I have, therefore, prepared Table VIII. to show what has been my own experience in this matter. This Table gives the actual sum spent on the maintenance of various parts of the plant of the works of the Kensington and Knightsbridge Company during the last four years out of the seven years that this Company has been supplying electrical energy. I have given in the Table the original cost of each part of the plant, and have worked out the annual percentage cost which the maintenance bears to the original cost. As some of the steam engines and boilers of this Company have been at work seven years, and the bulk of the plant has been at work five years, sufficient time has elapsed for the maintenance cost to have settled down to the figure at which it is likely permanently to remain. As might be expected, the upkeep of the boilers and the accumulators has been more costly than that of any other portion of the plant, but in neither case is the amount as high as I expected it would be. The noticeable feature is the very small sum spent on the upkeep of the engines, of the dynamos, and of the mains.

TABLE VIII.—*Cost of Maintenance of Works for a Period of Four Years*—1890, 1891, 1892, 1893.

Description of plant.	Original cost.	Spent on maintenance in four years.	Per cent. per annum on cost.
	£	£	%
Buildings	16,598	429	0·65
Boilers	8,124	1,704	5·23
Engines	9,900	704	1·77
Dynamos	8,660	264	0·76
Other plant	12,868	968	1·9
Accumulators	15,115	1,968	3·25
Mains and services ...	65,167	952	0·36
Meters	6,549	628	2·5
Total	£142,981	£7,616	1·35%

The cost of upkeep of the engines is confined to the substitution of small parts as they wear by new parts supplied from store. It will be seen that the upkeep of the dynamos is almost *nil*; but I must direct particular attention to the small sum spent on the inspection and maintenance of the mains, as this vindicates my often-repeated assertions that a well designed and conducted bare-copper system must cost less to inspect and maintain than any system of continuously insulated cables. At any rate, the sum expended on mains, as shown in this Table, is an outside sum, as it includes many alteration items, which can hardly be considered as fair wear and tear, but rather in the nature of improvements, and thus chargeable to capital.

The maintenance sum spent by this Company has been sufficient to keep the plant in absolutely as good order as when it was first put down; and, as I have just said, in some cases has enabled improvements to be introduced which have been charged to revenue. This gives me hopes that future experience will not show any marked increase in these percentage rates, but rather the reverse; so that the ideal figure I have proposed of 0·4d. per unit, which on 5,000,000 units will yield the very respectable sum of £8,300 per annum, will be a sufficient sum to maintain the entire plant in perfect working order for ever.

I have now taken you through all the items of cost of an electrical supply works, and have endeavoured, as far as possible, to compare what has been done up to date with an ideal possible standard. Whether this standard be ever reached or no, I think it will serve the useful purpose of holding before you a goal which we may all strive to attain, and that without the necessity for bringing out any wonderful revolutions in our practice, or, in fact, doing anything but intelligently perfect and use our present appliances.

I hope my efforts in preparing this Paper will be appreciated by those to whom it is addressed. I personally have the warmest sympathy with, and admiration for, the work of the large number of young electrical engineers who are now scattered over the various supply works, and to whose efforts we are indebted for the very marked advance in economy that I have this evening brought before you. I sincerely hope and trust that the means I have adopted of circulating the Paper before the meeting will have given time to these works engineers to appreciate some of my points, so that we may have the advantage of having the important questions that I have raised, ventilated and discussed by those who are most competent to do it, namely, the resident engineers of electrical supply works.

In conclusion, the art of electrical supply has now passed from the stage of estimate and talk into that of commercial enterprise. What is to be learnt from the tabulated results of commercial enterprise I have endeavoured to bring before you with the main object of showing what are the possibilities of cheapening electrical supply in the immediate future, as I feel strongly that if we electrical engineers are to play our part in making this an electrical age, the electrical supply must be so carried on that the poorest can avail themselves of it as well as their richer neighbours. Once this is done, many of the problems of electrical supply will be simplified. I think most engineers will agree that it is a far easier and more satisfactory matter to supply electricity to small consumers than to large ones, and it is certain that when electrical supply can be extended to small tenements it will have a very powerful influence in increasing the material comfort of the poor. In fact, I may say that until electric supply becomes general I consider we have only touched the fringe of our task. I say this because I think it quite possible that some of my critics will divert the discussion into side issues. I hope I have made it clear, however, that it is only in a careful study of the wider problems connected with the economical use of fuel, economical use of steam, and economy in maintenance that such future cheapening is to be looked for.

I cannot conclude this Paper without expressing my thanks to the very large number of gentlemen who have assisted me in my labours. In order to get together the data necessary for the production of this Paper, I have had to visit a number of stations, and write a large number of letters to the engineers of stations which I could not visit. As it may be the wish of many of these gentlemen to preserve their anonymity, I do not thank them by name. As regards stations with which I personally am closely connected, the importance of anonymity is not so great, and I have therefore the pleasure of stating that much of the splendid results that have been obtained from some of my own stations—the figures of which, no doubt, some of you have recognised in the Tables before you this evening—are due to the continued hard and intelligent work of Mr. Miller, the resident engineer at Kensington, Mr. Barley, the resident engineer at Knightsbridge, and Mr. Pott, the resident engineer at Chelmsford.

PROF. A. B. W. KENNEDY'S PRESIDENTIAL ADDRESS TO THE INSTITUTION OF MECHANICAL ENGINEERS.

(Concluded from page 15.)

Those questions about the running of a lighting station which are essentially matters of mechanical engineering group themselves mainly in three sections, according as they relate to (1) security, (2) efficiency of regulation, and (3) economy of working. It is obvious that the fundamental question of the choice of an electrical system in any particular case connects itself with all three, but this fundamental question I do not propose to discuss here, partly because it is not a matter which can be discussed in a few words, and partly because it is to so very large an extent an electrical matter that it does not fall well within the scope of my present address.

Of the three points I have put security first, because no doubt the absolute certainty that nothing short of a boiler explosion or of the burning down of a station shall stop the supply of current is really the very first condition of supply. Clearly with any machinery the burning of an armature, the seizing of a bearing, or the breaking of a shaft, are possibilities which may have to be faced at any moment. They seldom occur—very seldom happily—but sooner or later one or other will come about, and the engineer in charge has to be provided with means for preventing any such accident having more than the most transient effect on his light. Of course, the existence of proper reserve plant, such as I have already mentioned, is the first necessity of the case. Scarcely less important, however, is the necessity that such reserve should be almost instantly available. Where all the plant is running in parallel, *i.e.*, where all the dynamos or alternators are working straight through the same pair of omnibus bars on the switchboard, it will very often happen that the other machines which are at work may of themselves be able, at least for a few minutes, to take up the load of the one which has broken down, and so to allow time for another machine to get started. It may quite well happen, however, that these machines may be themselves running very nearly at full load, and that the broken-down machine may have had so large a load upon it that this is impossible. In any case a large machine, say 400-H.P. or more, cannot be started and got on circuit in a few seconds, and seconds are of importance in these cases. For this reason, in stations which use alternating currents it is usual, and

Digitized by Google

probably necessary, to have one reserve machine always warmed up and running round at half speed, so that it is merely a matter of opening a stop valve to let it away in a condition ready for putting on circuit, although the synchronising-in is unfortunately always a matter which may cause some minutes' delay. In continuous current stations it frequently happens that a battery is used which can give so high a discharge for four or five minutes as to take the place—along with the machines remaining on circuit—of the machine which has given way, until another machine has been started and put on. So far as it goes, this is, no doubt, a great advantage, but it must be remembered that the mere existence of a battery, and even of a battery quite sufficient for helping in day and night light loads, is not sufficient to ensure that the battery shall be available for help in this fashion. Two details are easily seen to be essential when it is remembered that the failure may occur during the hours of full load. As the volts are highest at such a time, the battery must not only have sufficient capacity, but also must have a sufficient number of cells to give in discharge the full E.M.F. of the station, and this will not be the case unless the engineer has specially provided for it by an unusually ample number of cells. Secondly, the battery must have been fully charged beforehand so as to have the maximum E.M.F. per cell available. This involves that the battery charge should have been completed during the day, before the hour at which full volts could possibly be required from it in case of any accident. A battery which could only discharge heavily at 215 volts would be practically no use whatever as security against a drop of pressure after an accident which might possibly occur at 230 volts.

In an alternating current station where the machines are not run in parallel, but where each alternator supplies current to its own separate circuit or bunch of circuits, the sudden failure of a machine must instantly cause extinction of light in the circuit affected for the fraction of a minute which must elapse before the circuit can be thrown on to other machines, or the few minutes which it must take to get another engine started and plugged on. In a station worked on this plan however, the machine which is turning round as stand-by can be kept excited, and giving the volts corresponding to its speed, and can be plugged on in readiness, so that the circuit from any machine which has broken down can be instantaneously switched on to it, and it can be run up at once to full E.M.F. without, of course, any of the delay which would be unavoidable if it had to be synchronised and put in parallel. It has also to be borne in mind that in cases where a number of alternators are running in parallel the breakdown of one may tend directly, in certain cases, to endanger all the others—a trouble which does not exist if circuiting be used. On the other hand, the circuiting system causes inevitable, if slight, flickers in the light, which are quite avoided by running in parallel. It also necessitates the use of comparatively numerous circuits, as no one can be allowed to carry more than from 30 to 50 kilowatts at a time when it is switched on or off.

It must be recognised that in one matter the requirements of security and of economy are more or less opposed. If an engineer is quite certain that whether by the help of batteries or otherwise he can bring his reserve into action so promptly that the worst breakdown will not spoil his lighting, he will no doubt always run each unit of his plant as nearly at its full capacity as possible. But if for any reason he cannot be so sure of his reserve, he will gain greatly in security by running his plant always so far under its maximum that he can distribute the load of any one unit for a few minutes over the others without endangering them. But, of course, this is practically equivalent to underrating the whole capacity of the plant by a considerable percentage, probably 20 per cent., and consequently of increasing the capital cost of the plant per unit of normal maximum output by just the same percentage—a result which one does not wish to face.

I have spoken of possible breakdown of engines or dynamos. There are, of course, other accidents to be provided against. Short of a boiler explosion, the most serious of such accidents would doubtless be one occurring to a steam-pipe. The physical consequences of the actual bursting of a steam-pipe are not of course, the matters at present under consideration. In all probability such an accident would disorganise any station, no matter how well arranged. But short of the actual bursting of a pipe many things may happen which may render it necessary to shut down a certain portion of piping. It is generally necessary, therefore, to provide any lighting station with something in the nature of a ring-main system, or its equivalent, by which any engine in the station can be supplied with steam from two directions. In a properly arranged ring-main system it should be possible to disconnect or cut out of use any section of steam-pipe which may be giving trouble without stoppidg a single engine. Of course, it is not necessary to provide pipes so large that under these conditions there should only be the normal drop of pressure between boilers and engines. One can put up with an extra drop without grumbling if it only occurs under these circumstances. It is inevitable, to reach the required degree of security in this matter, that the steam-pipe should be fitted with a very large number of valves, and these are undoubtedly objectionable if only on account of the very considerable loss by radiation which is almost inevitable from their covers and flanges. But after all, the making of good steam joints in large pipes at 150lb. pressure is nowadays a very simple matter, and the unavoidable complexity of the arrangement is more than counterbalanced by its usefulness.

The duplication of the steam-pipes must obviously extend to the boilers as well as to the engines. The hanging up of a safety-valve, the blowing of a mudhole joint, the bursting of a tube, or any one of half-a-dozen other such accidents, may put a boiler suddenly *hors de combat*. It must be possible, therefore, at the shortest notice, to cut out any boiler without interfering with the working of the rest. Fortunately, boilers can be forced more readily than engines or dynamos, and such an accident could almost always be met by forcing the remaining boilers somewhat.

Reserve in boilers stands thus in the same position as reserve in machines, except in so far that the boilers can be more easily forced, as I have just pointed out. With them, however, as regards security of working, there comes in an even more difficult question than that of reserve, namely, that of readiness for emergencies other than breakdowns. Even in London, where a fog may cause the load on a station to increase ten times in as many minutes, there is practically no difficulty in getting the engines started quickly enough. It is otherwise with the boilers, which, although so easily forced when actually in work, are terribly sluggish in getting up steam, as compared with the rapidity with which unexpected darkness used to come over London, and doubtless will come over again when the sun has recovered from its present attempt to outshine all artificial lights. At the most inconvenient time for a breakdown, namely, the time of full load, the engineer knows at least that an engine or dynamo accident can hardly affect him to more than 15 or 20 per cent. of his whole work, of which at the worst a considerable portion can in most cases be taken up by the remaining plant. But the most inconvenient time for a fog to come on is at light load, and then the increase coming on in a few minutes may be anything from 500 to 1,000 per cent. ! And the engineer must be able to meet this in June as much as in December, and with even less notice. Practically this means that even in summer enough boilers must be kept under steam—if not at full pressure at something near it—to be able to take up this enormous increase of load in ten minutes, as soon as ever their fires are brought forward and their dampers opened. (I am speaking here of such cities as London, or Manchester, or Glasgow. Of course I know that there are happy places like Rome or Aberdeen where fogs are unknown, and where therefore all this provision against them is unnecessary.) I need hardly point out to you, after going over all these points, that it is improbable that the fuel consumption per indicated horse power-hour in electric light stations will ever reach, or can ever reach, anything like so low a figure as has often been reached in first-class steamers, where the engines and boilers work on continuously day and night at pretty much their most economical load.

I will mention just one more point as to security of working in a station—the feed arrangements. Here in London I have several times run considerable risk of stoppage from this cause. A duplication of feed pumps and pipes is an obvious precaution, and one that probably every one adopts. But few of us can keep water stored in sufficient quantity to last for more than three or four hours at full load, so that without special arrangements we are liable to be extremely inconvenienced by any accident happening to the mains of the water companies outside, which may compel them, on short notice or even no notice at all, to cut off the supply for a few hours. The best arrangements to meet this contingency vary in different places, but the engineer must not lose sight of the fact that the difficulty is one which may occur at any time, and from causes altogether beyond his control and even knowledge.

Outside the station the question of security comes in in connection with the mains. To a certain extent every station which uses either high or low tension feeders has some reserve in their very number. When a company has more than one station, trunk mains led from one to the other are also a considerable security, as well as a great help to economy. Mr. Frank Bailey, of the Metropolitan Electric Light Company, has carried out a most excellent ring or looped main system on his high tension distributors, by which he can make sure that any consumers can be supplied two different ways round the circuit, so that any accident to the mains may cause a minimum of inconvenience to a minimum number of consumers. In ordinary low-tension distributing networks, the same result should be aimed at, although it cannot generally be obtained in what the mathematicians would call so " elegant " a manner.

Many points occur in connection with the arrangement of electric mains which might be discussed in this connection, as to the means for isolating and testing them, the desirability of putting large sections into parallel or working them separately, &c., but these matters rather lie on the electrical than on the mechanical side of the subject, and I must abstain from discussing them here.

Digitized by Google

I have next to speak of the *regulation* of an electric lighting station, as forming along with its *security* the two matters which chiefly affect the consumer of electrical energy. All that the consumer cares about is that the pressure in his house should be steady to the eye, and should be not less than its nominal value and not very greatly above it. In all stations working on a large scale this constancy of pressure in the consumers' houses necessitates a constantly varying pressure at the station in order to make up for the loss of pressure in the mains, which is itself—wholly or in part, according to the system of supply—dependent on the amount of current passing through them. In an ordinary alternating current station the pressure at times of maximum load exceeds that at times of minimum load by about 5 or 6 per cent. In an alternating current station with low tension distributors the excess may be about 12 or 15 per cent. In an ordinary low tension station with three-wire system it may often be 20 per cent. The actual figure of course depends on the current density permitted in the copper, but the figures I have given illustrate the sort of percentage which different engineers have found it advantageous to adopt on a large scale.

The primary requisite for proper regulation is obviously enough that the engineer shall know the actual value at each instant of the pressure which he desires to keep steady. In every case where low tension distributing mains are used this pressure is the pressure at certain feeding points or at certain sub-stations, and it is best known at the central station by direct indication—bringing back pilot wires or potential leads from such points direct to the station, and connecting them to suitable voltmeters there. In these cases the regulation consists in so running the machines that the pressure indicated by these voltmeters is always kept at the desired amount. What appears to me a less satisfactory method is sometimes adopted, namely, the determination by calculation or by experiment of the loss of pressure corresponding to each output, adding this loss to the normal pressure, and regulating the dynamos to the corresponding sum, transformed if necessary. Apart from the fact that in this case the pressure actually received by the consumer is only estimated and not really measured, so that the thing measured is not the really important quantity, there is the additional drawback that the regulation is to a varying quantity instead of to a constant one, and is therefore less likely to be thoroughly satisfactory.

In cases where distribution is by high tension with isolated transformers, there is, of course, no direct means for keeping the pressure constant in the consumer's premises. If the distance between the nearest and the furthest consumer on any circuit is much less than the distance from the station to the nearest consumer, there may be a reasonably good regulation by the indirect means I have just described. In the case where the distance from the station to the nearest consumer is small in proportion to the distance from the nearest to the furthest, no such regulation is practically possible, and, in fact, in these cases the section of the copper must be made so large as to reduce the drop of pressure within negligible limits.

By one or other of the methods which I have mentioned, and preferably, no doubt, by the use of pilot lines, the engineer in the station knows to what pressure he is to work. In every case the station must work at a varying pressure, although in some instances the variation may not be great. The highest pressure must occur always at the times of greatest load. Several means are at the disposal of the engineer for varying this pressure. Best of all, I think, as being most convenient and most easily controlled, is the provision of sufficient additional resistance in the fields of the dynamos or exciters to enable the magnetic field to be altered by the mere moving of a switch having many contacts. Of course to a certain extent this method wastes energy; but the quantity so wasted is so very small in proportion to the whole that it is not too high a price to pay. The switches can be placed upon the switch gallery so that the whole of the regulation may be done by the man in charge there, and be quite removed from the actual control of the engine-drivers. In order that this method may be satisfactorily carried out, the engines must be so arranged that they can be run entirely upon their governors, the stop-valves being opened fully as soon as the machines have taken up any load. In this connection it is worth while noticing that for continuous-current machines constancy of speed—which is, of course, to be distinguished from steadiness of speed, quite a different matter —is not in itself in the least a thing to be insisted on. The governor must be so set as entirely to prevent the engine racing in the case of a sudden short circuit or other breakdown. But apart from this, an alteration of five per cent. or more is not a matter of the least moment. In fact, for practical purposes it is generally better that the governor should not be too finely set. Of course, it may quite well happen that in the case of any one engine it may have to run throughout nearly its whole range of power at the same electrical pressure. If, therefore, the governor is so arranged as to allow of a drop in speed at full load, the field resistance must be so proportioned that notwithstanding this drop it can either keep the pressure constant or allow it to be increased within the desired limits.

A much less satisfactory method of regulation is by means of the stop-valve—that is to say, by the engine-driver actually opening or closing his main steam-valve according to the pressure required. If this has to be done, each engine-driver must be able to see the pressure to which he has to regulate, and instead of regulation taking place by an easily moved switch in the hands of one man, it has to be carried out by the action of half a dozen stop-valves in the hands of, perhaps, as many different men. The enormous voltmeters which were made a few years ago, and, I believe, are still used in America in some places, having faces so large that they can be seen all over an engine-room, were designed in connection with this particular method of regulation. Regulation by field resistance was perhaps then not so well understood as it is now. At any rate there can be no doubt which method is the better on all practical grounds.

I have been speaking of efficiency of regulation so far as it affects or is affected by the gradual alterations of load such as are represented upon the diagrams on the wall. At times of full load this is practically the only matter of importance, because at such times any sudden increase or decrease of load are small proportionately to the whole load of the station. But in a station where the load every afternoon is, say, 1,000 kilowatts, it may quite well happen that in the early hours of the morning or during a bright forenoon the total load is little more than a hundredth part of this. In such a case the sudden throwing on or off of a motor without proper starting resistance, or even of a photographer's arc lamp under similar conditions, may increase or decrease the actual output by 20 or 30 per cent. or even more. Such variations are most often excessively sudden and of extremely short duration, so that they are particularly difficult to regulate for, and one must only be thankful that in the nature of things they can only occur at times when a little flickering of the light is not noticeable. In stations which are able to use batteries, there is no doubt that the battery acts practically the part of a flywheel in respect to these rapid variations.

I now come to my last section, namely, that of economy of working a station, still looking at the matter, of course, from the point of view of the mechanical engineer. Economy of working covers two sets of questions. There is first the reduction of direct cost of coal, oil, stores, water and maintenance per unit or per horse-power hour, and secondly, the obtaining of the greatest possible ratio between the net useful and the gross indicated horse-power. Taking these matters in their order, the question of coal naturally comes first. In an electric-light station the cost of coal averages not far from four-tenths of the total working expenses. While, however, this matter is so important a one, it is yet one on which so much has been said and written that it need not detain us long. There is no one type of boiler, at least I do not know of any, which is better than all others under the conditions of an elecric-light station. Indeed, I would go so far as to say that from the point of view of economy there are five or six types of boiler which with equally good stoking will yield equally good and in every respect first-class results. Of course any type of boiler may be badly arranged or badly proportioned, may be under-worked or over-worked, but if an engineer is not capable of so proportioning the boilers of whatever type he adopts as to give thoroughly good results, or of finding out whether his results can be improved, he had better at once take to some business which is less complicated than that of scheming an electric-light station. It may no doubt sometimes be necessary in order to get a specially large output out of a boiler to provide it with one of the thousand infallible nostrums for that purpose. So far as my own experience has gone however, I think that almost anything can be done with a really well-designed boiler, if only the engineer in charge knows how to handle his dampers and how to deal with his particular fuel under the conditions where coaxing is required. I have lately had some remarkable illustrations of the way in which a particular boiler could have its output increased 60 per cent. by the application of certain particular apparatus to it, and an exactly similar boiler could then, when the stoker had found out how to manage his fires, give exactly the same increase in output without any change being made in it whatever!

One thing which tells very much against the economy of an electric-light station in respect to its evaporation per pound of fuel is the extent to which, during all day in many places, fires must be kept alight and pressures up in boilers capable of giving 8 or 10 times the actual output, and the extent to which in all stations fuel must be expended in getting boilers ready for the heavy load which comes on only once in 24 hours. These stand-by losses are not, as one would think, losses which get less as the output of the station increases, for the proportion which the stand-by boilers will bear to the actually used boilers at any moment will be practically constant whatever the output of the station. I have found that the total stand-by losses can be reduced in some cases to under 8 per cent. of the total fuel. Below this I have not yet succeeded in coming,

Digitized by Google

although I hope a lower ratio will be obtained in the future. I am afraid it is often considerably more than 10 per cent.

I believe that a far larger proportion of fuel waste in a station occurs through causes beyond the boilers than in the boilers themselves—that is to say, it is much more easy to get a good evaporation per pound of coal than a small consumption of water per indicated horse-power. Of the causes which contribute to this the first is undoubtedly the very great loss which occurs by condensation in the steam pipes, and by leakage through drains and other valves before ever the steam gets to the engines at all. This is probably much greater in proportion in an electric-light station than in most other places, because the requirements of security which I have already discussed necessitate the use of a very elaborate system of steam pipes, much more elaborate than is found in any other works. Not only does this system of steam pipes present a large radiating surface, and in various ways offer particular facilities for cooling the steam, but also the absolute necessity of keeping the pipes clear of water at at all times, so that any section of them can be used safely at a moment's notice, involves the use of drain-pipes and cocks. These necessary adjuncts to a system of steam-pipes, along with the apparatus which we call by courtesy steam-traps and use in connection with them, are a continual source of waste and annoyance to the engineer. The drain-cocks get left open, or if they are shut they leak themselves open, the steam-traps require more looking after than the whole of the rest of the machinery put together, and altogether the whole system of pipes, drains and traps, probably cost us in many cases 10 per cent. of our whole fuel. In some experiments which I recently had made I have found the proportion to be 8·8 per cent., and I have reason to think that it is often far greater. I know of no heroic remedy which can be applied to the matter. Probably we have not in general paid sufficient attention to the proper covering of the pipes, including their flanges and the flanges of the stop-valves. Certainly we have not somehow succeeded in obtaining steam-traps which will really work with any approach to permanent satisfaction under the trying conditions of every-day work. I hope that the use of superheated steam may be found very largely to reduce this particular cause of waste. Apart from this matter, I know no reason why any engine in an electric-light station should not work every day and every hour at exactly the economy which the same engine reached on special trials made at the same load under the strict conditions of a specification. I have, in fact, on many occasions compared the running of engines in this way with the running of the same machines at the same loads on their original tests. When I have subtracted the amount of steam used for the feed pumps, the difference was never greater than I have found to be covered by the condensation losses which I have mentioned. Of course, it it necessary to remember that engines working in a central station at very varying powers cannot be expected to give average results equal to those obtained at full power on trial. The results should be compared on the basis of tests at corresponding powers, and in order that this comparison may be carried out I always have a series of graduated tests made before taking over machinery.

After the cost of coal comes the cost of oil, water, and stores. These three items together cost in the average about one-fifth as much as the cost of coal alone. There is not much which can be said in circumstances like the present on the question of economy in this part of the expenditure, which really depends altogether on the good management of the engineer in charge. Such matters as the filtering and re-using of lubricants, and as the prevention of all needless waste of water, are obviously to be considered. It is, perhaps, generally sufficient for the engineer to find out the very lowest cost under these heads obtained in any other station, and to believe he can do a little better if only he tries hard enough. Cost of repairs and maintenance, still more than that of oil and stores, is one about which little can be formulated. There is no one type of engine or dynamo, so far as I know, that can be definitely said to be ahead of all others in respect of the fewness of its repairs. There are several types of machine which in the hands of careful engineers certainly give very good results, although it is somewhat difficult to compare the published figures under this head on account of the number of electrical stations which are still wholly or partially in the hands of their contractors, and in which, therefore, the full amount of repairs does not appear in the accounts.

I have mentioned that the economy of a station depends on two sets of considerations, namely, the actual quantity of fuel, stores, &c., per indicated horse-power hour; and, secondly, on the actual relation between the useful power and the gross power. It is obvious that it would be of no use to save 10 per cent. on the coal per indicated horse-power hour if that saving involved the use of machinery whose mechanical efficiency was 10 per cent. lower than it would otherwise be. This brings us face to face with the question which is always one of the most important to the engineer, namely, when he has got his horse-power in his engine as cheaply as possible, how to arrange so as to utilise the largest possible proportion of the horse-power thus obtained. The utilised horse-power is represented, in the case of an electric-light station, by the energy passing through consumers' meters and paid for by them. Between this useful horse-power and the indicated horse-power of the engine there comes first the loss in the engine itself, then the loss between the engine and dynamo, thirdly, the loss in the dynamo itself, and fourthly, all the losses between the terminals of the dynamo and the consumer's meter. As to loss in the engine itself, this does not appear to vary very much in different types of engines of first-class make. Approximately, it may be taken as about 10 per cent., sometimes a little less, of the full power of the engine, and as remaining very nearly constant at all powers as long as the speed is constant. Thus the mechanical efficiency of an engine which is 90 per cent. at full load, will be only about 80 per cent. at half load. The efficiency of a dynamo at full load is much higher, it may be as much as 95 per cent., and may be still 90 per cent., far below half load. Thus the ratio of electrical to indicated horse-power of a first-class steam-engine and dynamo may be 85 per cent. at full load, and something like 76 per cent. at half load. This assumes that the engine drives the dynamo direct, and that there is therefore no loss in transmission between them. I must confess that it remains a complete puzzle to me, a puzzle of which I have never found any solution, why engineers should wish, in addition to these practically unavoidable losses, to spend certainly 5 per cent., and on the average probably much more, of the whole of the power in their station in moving ropes or leather belts which have nothing whatever to do with the ultimate result, and which take up an enormous amount of space. The true solution of the matter really appears to me beyond all doubt to be either the use of quick running engines, as is so common in this country, or of slow running dynamos, as is so commonly the case on the Continent. I am, of course, here speaking of driving by steam-engines, not by gas-engines, in which latter case a number of other considerations come in.

As most steam-engines take practically the same power *per revolution* to drive themselves, it is obvious that at low powers an increase of mechanical efficiency will be obtained by running at a less speed than that used for full power. This, of course, requires a specially-arranged adjustable governor and a wide range of control in the field regulation. But I think it is worth doing in many cases.

The losses between the dynamo terminals and the consumers' lamps are, in a low-tension system, simply the losses in the leads. In a high-tension system they cover the losses, in general very much smaller, in the leads but also those in the transformers as well. This is not a place nor a time for entering on a discussion of the relative merits of high and low-tension systems—a matter which to anyone who is not a partisan of one or the other could certainly not be adequately discussed in any time short of the whole of that which has been occupied by this Paper. Moreover, I need hardly point out that the choice of a system cannot possibly rest upon any one single point, such as the relative magnitude of the losses from a single cause. At present, so far as the figures to which I have access go, it may be interesting to you if I mention that in the case of a low-tension system where the maximum proportion of loss in the feeders is allowed to reach 20 per cent. or thereabouts, the actual average loss of energy throughout the whole year amounts to about 10 per cent. This is, of course, entirely due to ohmic resistance of the feeders themselves and of the network. I have no statistics by which I can compare feeder losses only in an alternating-current system with the figure I have just mentioned, but so far as those figures go to which I have access apparently the total losses both in mains and transformers in a high-tension system are not less than 25 per cent. of the energy generated. It is probable, indeed I think it is certain, that this figure will be very considerably reduced in the cases where banked transformers are employed with low tension distributing mains. I hardly think, however, that it can be expected that the total losses will ever be so low as with a low-tension system.

I have already alluded to the extent to which the economy of a station is affected by the average load at which its units are run. To attain the greatest economy it is obviously advisable that the machines actually at work at any moment should all be as nearly as possible fully loaded. The extent to which this can be actually reached in practice is shown in Diagrams 5 and 6. In one of these cases it will be seen that the average load during 24 hours is 78 per cent. of the load which would have been reached if the same machines had run the same number of hours each at its full power. In the other case the percentage is 58. What this particular percentage may be always depends on the exact relations between the load and the size of the units, and therefore in any station may vary very greatly at different times of the year. It is, however, not at all as easy as has often been thought to make the load factor, to use the expression in the sense of the above ratio, very high. I find it difficult enough in many cases, even with the use of comparatively numerous units, to keep it up to an average even of 65 per cent. Of course, it has to be remembered that whether or not it is economical, the station engineer has to make certain that he has sufficient plant running to take up the work as

Digitized by Google

it comes on. It is much the less of two evils that he should have every engine running every day half-an-hour before it is wanted, than that once a year he should be just too late with one or two of his machines. When the system of transformer sub-stations comes to be worked out practically a little more than it is at present, I believe that this load-factor problem will be found to be there even more troublesome than it is in the engine room, and that the capacity of the transformers which the engineer will consider it necessary

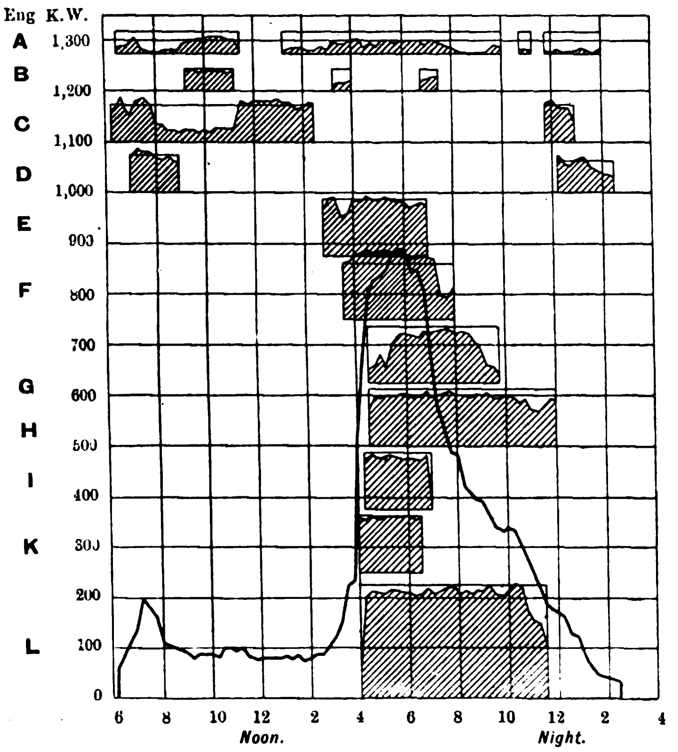

Fig. 5.—Diagram of Load Factors.

to keep on circuit in order that he may be always safe against breakdown of any of them, will be considerably greater than has been often assumed.

I would only, in conclusion, mention one other matter. The mechanical engineer may be supposed to be of all others one who will most naturally take to the making of measurements of all kinds. Any passion which he may have for this has ample scope in connection with electrical work. Electrical measurements, at least with continuous currents, can be made more easily, with simpler

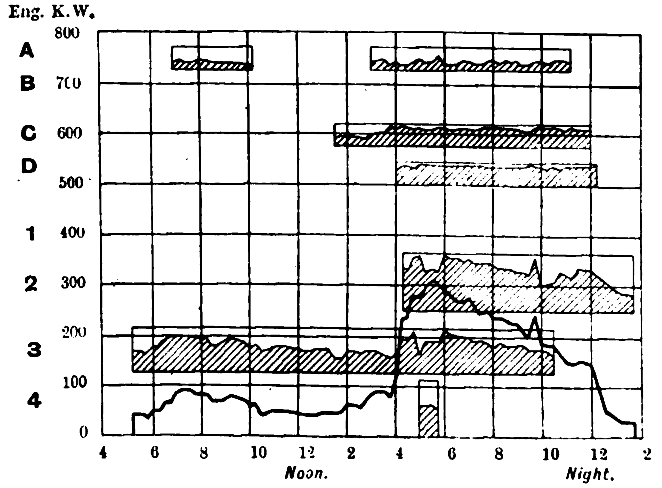

Fig. 6.—Diagram of Load Factors.

apparatus, and more accurately, than any other such measurements. I do not doubt that this fact has helped very much in the extremely rapid progress made during the last few years in matters electrical. Apart altogether from the more refined measurements which should be made from time to time for special purposes, there is no difficulty in getting continuous measurements, self-registered, with an average error of not more than 1 per cent., of the current sent out from each dynamo in a station. The average station volts can also be easily obtained with fair accuracy, and the amount of electrical energy developed at the dynamo terminals can thus be continuously measured as no other similar amount ever has been measured. This amount has to be compared with the amount of energy actually paid for, that is with the sum of the readings on the meters of consumers. Some of the electrical companies have published with their annual reports detailed electrical balance-sheets which show how very small the unaccounted-for quantity now is. In the case of the Westminster Electric Supply Corporation it was over 5 per cent. in 1891, 3·16 per cent. in 1892, and was still further reduced to 1·28 per cent. in 1893.

Unfortunately, with alternating currents, measurements are very much more difficult and troublesome, and, consciously or unconsciously, I think this fact has, to a certain extent, hindered their adoption. There are now, however, alternate-current wattmeters practically free from error due to circuit induction, and capable of giving results with quite sufficient accuracy under the actual conditions of station practice. I believe that very great improvements in the economy of alternate-current working will date in every case from the time when the station commences to make accurate determinations—based on something different from the engine-driver's hourly entries in a log—of the true energy generated and the way in which it has been expended.

I am sufficiently conscious of my own weaknesses to know that it is very dangerous for me to touch on the subject of measurements, especially at the very end of an address which has extended to so great a length as this. I will not, however, yield to the temptation, but will be content with simply having mentioned the matter. And in conclusion I will only say further that I hope the active electrical engineers among our members will forgive me for having spent an hour on such a very plain statement of matters familiar to them, if I have by this means been able to place before our non-electrical members some intelligible account of the problems at which we are working, looked at from their own point of view.

THE GLASGOW CORPORATION ELECTRIC SUPPLY.

The following is an abstract of the two evenings' discussion which took place on Mr. W. Arnot's Paper on the Glasgow Municipal Supply, which we published in our issue of April 27th :—

The PRESIDENT said it was rather difficult to discuss this Paper adequately, bristling as it was with figures, but he hoped that some of the electrical experts present would start the discussion. The mention of Prof. Kennedy's name as consulting engineer to the Corporation Electric Lighting reminded him that the University of Glasgow had seen fit to confer upon him the degree of Doctor of Laws. He was one of their honorary members, and he thought it showed the discrimination with which their honorary members were selected.

Mr. H. A. MAVOR said that although he considered the system adopted by the Corporation unsuitable for the work to be accomplished, he wished to compliment Mr. Arnot on the successful starting and working of the Glasgow station. He thought it would be evident to all engineers present that there was something wrong when the Glasgow Corporation, having undertaken to light not only the compulsory area (which is really all they had been compelled to consider up to this time), but the whole Royal Burgh of Glasgow, already in their first winter, had nine separate engines running in the station. Not only that, but the station, as at present constituted, could not be very much increased in size. The answer to that was, that another one would be started, and that it was better not to have too many eggs in one basket. Various other reasons which had a certain amount of cogency were pleaded in excuse. There was a limit to the size of stations, it was true, but there was also a limit to the possibility of starting electrical factories all over a city like Glasgow, and it seemed reasonable to suppose that in lighting such a city as Glasgow they should look to the experience of gas distribution as a guide to what they might do with electricity. He contended that there should be as many stations for electric lighting as gas works at present, because the problem was the same. He hoped at next meeting to bring forward some considerations which might interest the Institution with regard to some of the points Mr. Arnot had mentioned, especially with respect to the load curves and to the efficiency of the engines. It would be evident to anyone who looked at those curves that to use steam-engines, or any other source of power, for the production of electric lighting was not an economical thing to do. Most of the time they were standing idle and doing nothing. That was a kind of industry which was not a paying one, and therefore strenuous efforts had been made to find some means of storing the work of the engines so as to apply it to the circuit when the load curves reached that very high peak which occurred during the greater part of the winter between five and six o'clock in the evening. The attempt to do that had been so far unsuccessful. The use of accumulators was indicated in that diagram, and they would see how very small a part they played in the operation of the station. It was totally insignificant as compared with the work done by the engines, and, although they were useful in their way, he thought that on the whole the practice adopted in America would be followed in this country, and that batteries would not be used in lighting stations. There were some other points that he would beg respectfully to differ with Prof. Kennedy upon in his arrangement of the switchboard.

Digitized by Google

It seemed to him that his arrangements of the switchboard were very complicated—it seemed to him to be partly owing to the use of batteries, which led to more complication than was warranted by their use in working. Perhaps Mr. Arnot would be good enough to say what was the maximum loss in the feeders. He mentioned that under certain circumstances it was 25 volts or 12½ per cent., or thereby. Now, that was another matter which meant a considerable amount of complication on the switchboard. If there was a loss of 12½ per cent. between the generating plant and the most distant part of the system, that loss had got to be compensated for in the engine-room, and as the loss varied with the load the compensation would vary, and that necessitated constant watchfulness on the part of the attendant, and was one of the reasons why the continuous system was more difficult to work than the alternating current system.

Prof. JAMIESON said he did not agree with Mr. Mavor on many points, and especially that part where he said that they should have great big engines working at one big centre. He believed rather in using comparatively small engines, and consequently in being able to put in or take out power as the public demanded the same.

The discussion was then adjourned till next meeting, Tuesday, April 24th, when Mr. WILLIAM McWHIRTER, Faraday Works, Govan, who had moved the adjournment at the previous meeting, said the Paper had thrown a great amount of light on the Glasgow electric lighting installation, but it was just sufficient to cause those who had been able to follow it, or had since read it to desire more light. Still, there was time enough to remedy that in the reply on the discussion. He was satisfied that the right system had been adopted, but he could not for the life of him see why such an absurd voltage as 200 had been adopted. No one had been able to tell him why, but, perhaps, Mr. Arnot would do so. It would certainly have been much better to have adopted 220 or 230 volts. There would then have been a gain of 10 or 12 per cent. in the distribution of current, as also a very great gain in the working of the arc lamps. On the question of efficiency he had no doubt that the Glasgow installation showed a combined efficiency between the engine and the dynamo of 88 per cent. commercial, and 17·5 of water per horse-power, which, he thought, was all that one could desire. He did not think that, if they had adopted the alternating system there would have been got an efficiency exceeding 66 per cent., or something like that. There was thus a clear gain of 20 per cent. conversion, and there might be, as was said by Mr. Mavor at the previous meeting, a considerable loss in the distribution as compared with the alternating system. Coming to the question of accumulators, he could not say that he was at all in love with them in their present capacity in Glasgow. They were only able to carry on the lighting for a very short portion of the 24 hours. He did not know what the cost of the cells was, but it was probably something like £2,000; and he reckoned that the cost of maintenance would be at least 13 per cent.; indeed, it was nearer 30 per cent. That was something like £260. If they took that figure, he was quite certain that it would do more than fill up the interval over which the accumulators carried on the lighting. Then there was another thing to add. They would not get more than 85 per cent. efficiency from the accumulators, so that there was another 15 per cent. gone. After some remarks about faulty cells, the speaker went on to refer to the underground mains, regarding the insulation, of which he desired some information from Mr. Arnot. Speaking as a telegraph engineer, he remarked that he never saw in all his life such an attempt at insulation as there was in Glasgow; indeed, it was enough to make some old telegraphic engineers turn in their graves. He did not think that the resistance, as measured in megohms, exceeded three figures. Going on to calculate the loss, he was of opinion that it amounted to an ampere of current; and if that was going to waste it, meant 18 grammes of copper being removed from the positive conductor every hour, or about an ounce of copper every day. Whatever might be said of the other parts of the Glasgow electric light installation, the insulation of the underground mains was very far from what it might have been.

Mr. HENRY A. MAVOR said the first striking difficulty that appeared to him was what led the Corporation and their engineers to put down the station on the site which it occupied. All the coal had to be carted to the place, and there was no water available for the condensers. The ground was dear, and it was not by any means in the centre of the district which they were able to supply. By an arrangement which he suggested, he would have had four large engines and three balancing engines, or seven engines in all, making up a total of 3,000 H.P. In the Glasgow Corporation station, however, there were 13 engines, the biggest of which was one of 350 H.P., and the engine shop was more like a toy-shop. The load curve on December 26th, which was about the date of the heaviest curve of the year, between the 27th and 28th they would see how rapidly the load ran up from about one-fourth of the output of the station right up to the top inside of an hour. Could they imagine the trouble that was involved in the starting of no less than twelve engines between the top and the bottom of that load? It seemed to him a manifest absurdity. But he was like the man crying in the wilderness in hope that there was yet time to remedy the defect. There were still three engines of 350 H.P. each which it was proposed to lay down, and he hoped that the Corporation would be persuaded to put down as big an engine as the place would hold, and abandon that duplication of ridiculously small engines. Mr. Mavor further illustrated his position by reference to what he had seen in New York about four years ago, and the recommendations which he had made and had been successfully adopted. For such a station as that of Glasgow he considered that there was no necessity for having any engine smaller than 630 H.P., but as a concession to risk of breakdown he would put in one of 300 H.P. He estimated that the station had cost from £2,500 to £3,000 more than it would have cost if engines of the size which he spoke of had been put in. Further on he said that, looking to the large area still to be lighted, he thought it would only be fair to ask the Corporation to place the order with Clyde engineers, and ask them to make the next engines, and give them time to do the work.

Prof. JAMIESON gave his idea as to the extension of the Glasgow central station. He said he would place a suitable gas engine at each of the various points of the circumference of the system, and whenever the pressure lowered so as to indicate to the man at the station that the load was more than the central station could well develop and meet, then the men at any one or other of those points would each start up their gas engines in a few minutes; and for all the short time that it would take to do so those small plants and gas engines would meet the circumstances, and would have a very large extended area of electric lighting. He would have, in suitable positions, gas engines here, there, and everywhere all round the circumference or greatest radius from the central station, at which it could conveniently work, and convert that station very much on that plan.

Mr. SAM. MAVOR made a few remarks, which he chiefly devoted to the type of engine that had been adopted by the Corporation. Such engines had formerly been extensively adopted by the Admiralty for electric lighting; but for some years, he said, there had not been a single engine of that type ordered. He also had something to say with regard to the mains, and especially the insulation of each wire, serious fault having in some instances been found with the three-wire system, or with the mode of carrying it out.

Mr. ARNOT made a somewhat lengthy reply to the criticism to which his Paper and the Glasgow lighting system had been subjected. As regards the voltage adopted, he stated that when the Corporation took over the lighting then going on, there were already some 5,000 lights working at 100 volts, which they had to continue, otherwise a voltage of above 200 would have been adopted. There were no complaints coming to the station as to low voltage, but, if there were, inquiry would at once be made and the matter put right. He gave some further information as to the mode of working the feeder mains, and how the potential was kept up. No difficulty on that score had yet been met with, but if it did occur he had no doubt that they would be able to cope with it. Since reading his Paper, he had had some experiments made on a Sunday afternoon with some of the feeders, and he gave the results of the same, which were highly satisfactory. He admitted that, as suggested by Mr. Sam. Mavor, there was some difficulty with the negative wire, but they had not been troubled with leakage on their mains. He also said a word in favour of the engines employed in the station, and would not condemn them because elsewhere the crank shafts had broken from being too light.

PHYSICAL SOCIETY.

At a meeting of this Society, on April 27, 1894, Prof. A. W. RÜCKER, F.R.S., President, in the chair, a Paper

"On the Mechanism of Electrical Conduction:
Part I. Conduction in Metals,"

was read by C. V. BURTON, D.Sc. Considering a body not at absolute zero of temperature, the author shows that electromagnetic radiation would result in heat being degraded into a lower form of energy, if any parts of finite electric conductivity were present, and from the fact that our planet is not devoid of heat, deduces the following Theorem I.:—"In a region containing matter, there may be (and probably always are) some parts which are perfect insulators and some parts which are perfect conductors, but there can be no parts whose conductivity is finite unless every finitely conductive portion is enclosed by a perfectly conductive envelope." This conclusion is in accordance with Poisson's theory of dielectrics and with Ampère's and Weber's theories of Magnetism and Diamagnetism respectively. Theorem II. is enunciated as follows:—"In metals, and in other non-electrolytes whose conductivity is finite, the transmission of currents must be effected by the intermediate contact of perfectly conductive particles;" and as a corollary Theorem III. is given:—"If we suppose that in a substance at the absolute zero of temperature there is no relative motion amongst the molecules or amongst their appreciable parts, it follows that every substance at this temperature must have either infinite specific resistance (which does not imply infinite dielectric strength) or infinite conductivity." Fleming and Dewar's experiments on pure metals tend to confirm this. The author then shows why, on the intermittent contact hypothesis, a conductor is heated when a current flows through it. On the assumption that in ordinary conductors the relation between the electromotive intensity in the intermolecular spaces and electric displacement, is a linear one, and that the electric forces are small in comparison with the ordinary intermolecular forces, Ohm's law is deduced. A model is next described by means of which contact E.M.F. and the Peltier effect can be represented and explained, and in considering Volta E.M.F.'s the author points out that it is doubtful whether experiments in a perfect vacuum could decide the questions at issue in the contact-force controversy. The fact that the transparency of metals is much greater than Maxwell's theory indicates might be explained without attributing any new properties to the electromagnetic field by supposing the dimensions of molecule not quite negligible in comparison with the wave length of light.

Prof. S. P. THOMPSON thought the Paper had an important bearing on the kinetic theory of solids. He saw no reason why Ohm's law should be proved, for he regarded it as a definition.

The PRESIDENT said the author represented all actions as being due to collisions, thereby introducing the same difficulties as were felt in the

Digitized by Google

kinetic theory of gases, viz., that collisions would give rise to mechanical oscillations in the molecules of shriller and shriller pitch. Prof. J. J. Thomson had recently given an explanation of electrical phenomena by vortex filaments.

After some remarks on the visibility of molecules by Mr. Hovenden, Dr. BURTON, in reply to Prof. Thompson, said Ohm's law when expressed as $\frac{E}{C} = a$ *constant*, was really a law and not a mere definition.

A communication

"On the Design and Winding Alternate-Current Electromagnets,"

by SILVANUS P. THOMPSON, D.Sc., F.R.S., and MILES WALKER was read by the former. The Paper describes experiments showing that when the magnetic induction does not exceed 4,000 (C.G.S.) the pull exerted by a laminated electromagnet on its armature is the same whether it be excited by a continuous or by an alternating current of equal strength. For higher inductions the continuous current gives slightly greater force. Another experiment, made with solenoids and the U-shaped plunger of a Brush alternate-current arc lamp, gave similar results. In considering the question of winding alternate-current electromagnets so as to obtain a given excitation when the current is supplied at constant voltage, it is shown that the ampere turns are inversely proportional to the number of turns, for the impedance varies nearly as the square of the number of turns. One important property of such alternate electromagnets, when supplied at constant voltage, is that they give a fairly constant pull over a long range, for as the armature moves away from the magnet the current increases, thus counteracting to some extent the effect of distance. On the other hand, the alternating voltage required to obtain a given force is much greater than that needed with continuous currents. With the armature in contact with the core the ratio of the two voltages was found to be 170, whilst separating them by 9·2mm. reduced the ratio to 21·5.

Prof. PERRY pointed out that the constant pull of the alternate-current magnet followed immediately from the fundamental equation $e = re + n\dot{I}$ when re is small, for if e be constant, then $\dot{I}$, and therefore I and I^2 are constant. He was interested to see that the pulls for equal ampere-turns were the same, and indicated how the problem could be worked out mathematically when hysteresis was taken into account.

Mr. BLAKESLEY thought it better to fill the space on a magnet full of copper rather than use wire only just large enough to carry the current, for the loss of energy would be reduced. Some of the formulæ given might be put in simpler form.

Mr. SWINBURNE said an alternate-current magnet would only give constant pull in special cases. As another rule for winding alternate-current magnets, he said, wind the magnets as for continuous currents, and put a condenser in to take the same current, thereby reducing the voltage required.

Mr. BLAKESLEY said it would require a capicity of 600 microfarads to suit the magnet mentioned in the Paper.

Dr. THOMPSON, in reply, agreed with Mr. Blakesley that the condenser was impracticable in many cases.

Major R. L. HIPPISLEY, R.E., read a Paper on

"A Graphical Method of Constructing the Curves of Current in Electro-magnets and Transformers,"

and exhibited a machine for drawing the curves. The method of drawing the current curves step by step was explained. The machine for performing the process is illustrated in the Paper, and the curve for an electromagnet fed with alternating current shown. The case of a transformer without magnetic leakage is worked out at some length, and the curves of primary and secondary current determined.

Dr. SUMPNER said the author had used great care in working out a difficult problem more completely than usual. In cases such as arise in practice the R i term is small, and for this case Evershed showed how to determine the current curves of a transformer when the periodic state had been reached, some five or six years ago. He (Dr. Sumpner) had also shown how to graphically determine the current curves for circuits containing iron in 1888. The author's method was, however, of more general application.

Mr. TROTTER inquired whether the machine could be used in practical alternate-current problems, say, for example, to predetermine the E.M.F. curve of an alternator.

Major HIPPISLEY replied to the points raised.

LONDON CHAMBER OF COMMERCE.

At a meeting of the Electrical Trades Section held on Friday last at Botolph House, Eastcheap, Mr. Percy Sellon in the chair, the Secretary announced that circulars had been sent to the members, relating to the Antwerp Exhibition, but that no interest appeared to be taken in the subject. The question of the Acts of Parliament relating to the use of locomotives upon common roads was discussed. The Secretary said that he had written to the Commissioner of Police upon the subject of electrically-propelled carriages, who replied that he had been advised by his legal adviser that such vehicles were locomotives under the Acts. Mr. Sidney Morse gave the meeting some information with regard to the Vict. 41 and 42, and said that in the Acts of 1861 it was stated that locomotives were "likely to become common upon turnpike roads." The only definition of a locomotive was "a locomotive means a locomotive propelled by steam or by other than animal power." Mr. Morse thought that a vehicle containing its own motive power was not included. When a locomotive was put upon a cart and drawn by animals it would be allowed upon common roads without the attendance of two drivers and a man walking in front with a red flag, and a restriction of speed to two miles an hour. In the course of the discussion, it was observed that a test case had been tried some years ago at Woolwich, in which it was decided, that a steam tricycle came under the definition of a locomotive. Several members thought an approach to the Board of Trade or an attempt to amend the Acts would be premature seeing that the experimental attempts to construct electric vehicles for use on common roads have been very few, and have not been, as yet, attended with any marked success. It was suggested, with reference to a test case, that those who were interested in the subject should, if they thought fit, make a test case. Major Flood Page then entered the room, and took the chair, and said that he thought that electric traction of this kind was likely to come on very soon. It was eventually decided to write a letter to the Board of Trade upon the subject.

CORRESPONDENCE.

GALVANOMETER SHUNTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The Paper by Prof. Ayrton and Mr. Mather, which was recently read before the Institution of Electrical Engineers, upon "A Universal Shunt-box for Galvanometers," contains, as reported in your columns, a slip which may be noticed. In paragraph (1), speaking as of ordinary shunts, the writers state that, if the resistance of a galvanometer be say 1,000 ohms, the shunts of 1-9th, 1-99th, and 1-999th must have exactly 111·10, 11·11, and 1·111 ohms resistance. The figures, of course, should be 111·11, 10·101, and 1·001 ohms, as apparently they have in mind in the concluding lines of the paragraph.—Yours, &c., H. W. SULLIVAN.

29, Ladbroke-square, W., May 8, 1894.

METHODS OF MEASURING SELF-INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Alexander Russell, on page 5 of your last issue, describes certain methods of measuring self-induction, but does not mention to whom these methods are due. I therefore desire to state that the first method, in which the self-induction of a coil is compared with the capacity of a condenser, was first described by me, together with a number of other methods, in a Paper read before the Institution of Electrical Engineers on May 12, 1887. It has been found a most satisfactory method, and has been used by the students at the Central Technical College for the last seven years. The second method mentioned, in which alternating currents are used, has been known for a still longer time, and is due to M. Joubert.—Yours, &c,

May 8, 1894. W. E. SUMPNER.

PATENT AGENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your otherwise impartial article on Patent Agents you reflect somewhat unfairly on the backers of the Bill promoted by the Society of Patent Agents; and have been led astray, I fear, by the misleading article in *Engineering*, to argue in favour of the Institute's Bill. As one of the incorporators named in the first Bill, I can state that it was owing to the action of the Board of Trade and the Chartered Institute that we have been forced to come to Parliament at all, and you may feel assured that the gentlemen who backed our Bill had very strong grounds for doing so. As to the word "Act," to which you fairly take exception, you will find from the evidence we shall offer that it is an immaterial part of the Bill, the main object

Digitized by Google

of Mr. Alban Gibbs's Bill being to enable the whole profession to govern itself, instead of by a few individuals, as has been done illegally hitherto.

You quote from the memorandum of Mr. Warmington's Bill the words that it is not intended to create a monopoly, with evident approval, and refer to its promoters as being naturally jealous of their royal charter. You, and many others, are evidently unaware that the charter is practically inoperative, as the bye-laws under the charter have not been allowed by the Privy Council, owing to the opposition of patent agents who are not members of the Institute; and a further search into the provisions of the Bill would show you that a new meaning has been given by the promoters to the word "monopoly." I am writing simply to suggest that it is possible that all the honest, capable and honourable men in the profession are not in the Institute, and have no wish to be there until a very great change has taken place, and that it is advisable to suspend judgment in the matter until the other side is heard.—Yours, &c., J. Sinclair Fairfax,

Vice-President Society of Patent Agents.

433, Strand, London, W.C., May 8, 1894.

THE PRELIMINARY EXAMINATION IN "ELECTRIC LIGHTING AND POWER DISTRIBUTION."

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Following is a copy of a letter addressed by me to Sir Philip Magnus relating to the way in which candidates in the above examination are to have the results made known to them. This, and the reply thereto, will, I venture to think, be of interest to both teachers and students.

There is little doubt that the number of candidates will rapidly increase year by year, and it is to be hoped that at some future time the Institute authorities may see fit to modify their decision.—Yours, &c , W. Perren Maycock, M.I.E E.

Croydon, May 9, 1894.

[Copy.]

26, Stafford-road, Croydon, May 5, 1894.

Sir Philip Magnus, Secretary Examinations Committee, City and Guilds of London Institute, Exhibition-road, South Kensington, S.W.

Dear Sir: With reference to the newly-instituted preliminary examination in "Electric Lighting and Power Distribution," may I ask in what manner the results will be made known to the students?

It has been a matter for surprise to others besides myself that your Committee should have decided not to give certificates for this examination; but if each successful candidate is to receive a note from the Institute recording his success, that would, in a measure, make up for the absence of a formal certificate. From several years' workshop experience, I know there are very few electrical artisans proper who can hope to pass beyond the preliminary grade of this subject. To this numerous class of workers some duly authenticated acknowledgment of their having passed the examination in question would often prove of considerable value. If you will clear up this point you will confer a great obligation on other teachers than myself, and on the students, to whom I beg leave to make known this correspondence through the medium of the Electrical Press.—I am, Sir, your obedient servant, W. Perren Maycock.

[Copy.]

City and Guilds of London Institute Examinations Department, Exhibition-road, London, S.W., May 7, 1894.

Dear Sir: I need scarcely point out that the question of granting Certificates on the result of the Preliminary Examination in Electric Lighting has been carefully considered by the several Committees of this Institute, and that the rule on the Programme is the result of much deliberation. A list of candidates who may have passed that examination will be forwarded as stated to each centre at which they were examined, and it will be left to the Local Secretary to inform each separate candidate of his success or failure.—I am, dear Sir, yours very truly, Philip Magnus.

The Qualifications of a Canadian Electric Tramcar Conductor.—In addition to the usual requirements of electric tramcar conductors or "motor-men," the Montreal Street Railway Company has recently issued instructions that such men must be of a minimum height of 5ft. 5in., and weight 10st. 10lb. They must, in addition, be able to speak both languages—presumably English and French—so as to be able to make a proper report of each day's journeys.

LEGAL INTELLIGENCE.

Aldin v. Latimer Clark, Muirhead and Co.

Mr. Justice Stirling recently delivered judgment in this case. The plaintiff was the lessee of certain premises at Richmond, Surrey, and by this action he sought to restrain the defendants, who were the owners of adjoining property, upon which they had erected works for the purpose of supplying the town with electric light, from violating in various ways his rights as lessee. The plaintiff derived his title from a Mr. Munro, who was also the predecessor in title of the defendant Company. On July 1, 1878, Munro granted the plaintiff a lease of the premises occupied by him, with the buildings thereon, for 21 years, with a right of way over a portion of the adjoining property. Under a subsequent agreement the plaintiff, with the consent of Munro, erected an additional building upon the property, Munro advancing a portion of the cost and the plaintiff agreeing to pay an additional rent in respect of the shed so erected. Munro remained in occupation of the adjoining property down to his death in 1892. After his death his devisees sold the whole of his property to the defendant Company, who proceeded to erect thereon their electric lighting works. The matters mainly complained of by the plaintiff were the following:—(1) Interference with the access of air to the drying sheds used in connection with his timber business; (2) interference with the right of way granted by the lease of July 1, 1878; (3) interference with certain ventilators in the plaintiff's stables; (4) user of the defendants' property so as to heat the plaintiff's stables and render them unhealthy, and so as to endanger the plaintiff's premises and stock-in-trade and cause risk of damage by fire. The chief complaint, however, on the part of the plaintiff was that the works erected by the defendant Company injuriously affected the access of air to the drying sheds so as to render them substantially less useful for the purpose of the timber business which the plaintiff was bound to carry on upon the demised premises, and it was contended on his behalf that the acts of the defendants constituted either a derogation from the grants contained in the lease, or else a violation of the covenants for quiet enjoyment therein contained.

Mr. JUSTICE STIRLING, after stating the facts, said that the legal principle invoked on behalf of the plaintiff appeared to be recognised in several modern cases. In Robinson v. Kilvert a landlord let the floor of a house to a tenant for a paper warehouse, retaining a cellar immediately below. He afterwards commenced a manufacture in the cellar which required the air to be hot and dry, and employed heating apparatus which raised the temperature in the demised portion very considerably, with the result that some kinds of paper warehoused there were injured and made less valuable, though paper generally did not suffer. The landlord was ignorant at the time of the letting that the tenant was going to store any particular kind of paper which was liable to be deteriorated by heat which would not hurt paper generally, and it was held that the landlord was not liable either on the ground of nuisance or derogation from his grant, or breach of the covenant for quiet enjoyment. The result of these actions appeared to be that where a landlord demised part of his property for carrying on a particular business he was bound to abstain from doing anything on the remaining portion which would render the demised premises unfit for carrying on such business in the way in which it was ordinarily carried on, but that this obligation did not extend to special branches of the business which called for extraordinary protection. His Lordship concluded by saying that in the present case the lease was not merely granted for the purpose that the land demised might be used by the plaintiff for carrying on his business as a timber merchant, but it contained an express covenant binding him to carry on that business. In his Lordship's opinion, Munro became subject to the obligation to abstain from doing anything on his adjoining property which would substantially interfere with the carrying on of that business in the ordinary course; and that obligation bound the defendants as assigns from him, subject to the existing lease. His Lordship then proceeded to consider the evidence, and upon it came to the conclusion that some injury to the drying sheds had been made out, but not sufficient to justify the granting of an injunction. The plaintiff was entitled to an inquiry as to the damages he had sustained by reason of the buildings rendering the sheds less fit for use in the ordinary course of his business as a timber merchant.

De Livet v. Oliver and Others.

An application was made in the High Court for an interim injunction to restrain the defendants, until allotment to the plaintiff of 470.000 fully-paid £1 shares in the British Steam Generator and Refuse Utilisation Company (Limited) from selling, disposing of, or using the patent of the late C. de Livet. The plaintiff is the widow and personal representative of M. de Livet, who had invented and patented a means for burning and using refuse, of which accounts have recently appeared in the Press. Before his death, in August, 1893, he entered into an agreement with the defendants, Oliver, Sheridan, and Houldsworth for the purpose of forming a company to buy and work his invention. After his death an agreement was made between the plaintiff and the three defendants and the above-named Company for the sale to the Company of the invention in consideration of the allotment of the shares in question to the plaintiff. In March, 1894, the defendants entered into an agreement with the Atlas Syndicate, for the formation of a subsidiary Company for the purposes of taking and working a limited assignment of the patent within London and 20 miles round. The plaintiff stated that the shares in the original Company had not been allotted to her, and claimed an injunction.

The Judge decided that the plaintiff was entitled to an injunction until trial or further order, with costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Commissioners of Public Baths and Wash-houses for the parish of St. Saviour's, Southwark, require specifications and tenders for supplying and fixing an engine and dynamo at the baths in Lavington-street, London, S.E. Tenders must be in by 11 a.m. on the 16th inst. Further particulars appear in our advertisement columns.

——— The Corporation of Tunbridge Wells invite tenders for the construction, supply and laying down of the necessary plant and mains for the supply of electricity in the borough specifications, plans and forms of tender can be obtained from Mr. C. W. Cripps, the town clerk, to whom tenders must be delivered not later than June 6th. Further particulars appear in our advertisement columns.

——— The Guardians of the Portsea Island Union invite tenders for building workshops at the Union School and providing and fixing electrical fittings at the offices in St. Michael's-road. Tenders have to be in by 3 p.m. on the 16th inst.

TENDERS ACCEPTED.—The Chelsea Electricity Supply Company (Limited) have accepted the tender of Mr. J. Douglas, of Chelsea, for alterations to the sub-station in the Pavilion-road, Chelsea, for the sum of £391.

——— The tender of Messrs. Baxendale and Co., Manchester, has been accepted by the Visitors of the North Wales Counties Lunatic Asylum for the construction and maintenance, for a period of five years, of a telephone between the asylum and Glanywern Hall, Denbigh, a distance of about three miles.

——— The Stafford Town Council have accepted the tender of Messrs. Marshall, Sons and Co., of Gainsborough, for three horizontal engines for the electric lighting station.

——— The Worcester City Council have accepted the tender of the Brush Company for fixing the necessary mains for 26 arc lamps in several of the principal thoroughfares for the sum of £1,861, the Company agreeing to carry out the work as an extra on the terms of their present electric lighting contract.

TENDERS RECEIVED.—The Streets and Buildings Committee of the York Corporation have discussed the tenders received for the electric lighting of the City, and have passed the following resolution, "That any proposal for the electric lighting of the City by a system involving the use of low-tension currents only be not entertained." Six tenders were previously selected, and this number has been reduced to four, viz.:—The Brush Company, the Electric Construction Company, Messrs. C. A. Parsons and Co., and Messrs. Siemens Brothers and Co.

——— As mentioned in our last issue, the Lighting Committee of the Brighton Corporation have recommended the acceptance of Messrs. Crompton and Co.'s tender for the supply of engines and dynamos and accessories for the central station. The following were the tenders received :—

Easton, Anderson and Goolden	£6,503	0	0
Electric Construction Company	6,257	0	0
Johnson and Phillips	6,095	10	0
India Rubber Company	6,046	0	0
Siemens Brothers and Co.	5,930	0	0
Crompton and Co. (accepted)	5,550	0	0

——— The Improvement Committee of the Sheffield Corporation have recommended that the tender of the Sheffield Electric Light and Power Company (Limited) for the wiring of the Town Hall be accepted for the sum of £750, the Corporation to take the current from the Company's mains for twelve months from the opening of the building, the Company to keep the installation in good working order.

REMOVALS.—The offices of the Western and Brazilian Telegraph Company (Limited) and of the London Platino-Brazilian Telegraph Company (Limited) have been removed from 19, Great Winchester-street, E.C., to Blomfield House, London-wall, E.C.

——— The offices of the West Coast of America Telegraph Company (Limited) have been removed from 120, Cannon-street, to Winchester House, 50, Old Broad-street, E.C.

PLANT FOR SALE.—Messrs. Eardley, Holt and Co., of 28, Charles-street, St. James', London, S.W., advertise elsewhere electric lighting plant for sale, suitable for a country mansion or London house, the whole in sound working condition and equal to new.

"ANTI-SULPHURIC ENAMEL."—This material has been used in the accumulator rooms of the Carnaby-street electric light station of the St. James and Pall Mall Electric Lighting Company to protect the wood and metal work from the action of the acid fumes and spray of the batteries.

LITHANODE BATTERIES.—The Lithanode and General Electric Company (Limited) inform us that owing to recent improvements made in the manufacture of lithanode, all tending to reduce the cost of the material, they have decided to considerably reduce the price of electric lighting and other lithanode cells. The reduced price list can now be obtained of the Company, 64, Millbank-street, Westminster, S.W.

THE ELECTRICITY USERS' ASSOCIATION.—The first object of this Association according to its preliminary prospectus is "to provide members and the public generally with expert advice on all matters connected with the use of electricity." The other objects, advantages, rules, &c., appear to aim at providing the Association with clients who are to pay one guinea per annum for the privilege of receiving this expert advice. The circular which is being sent round suggests that electric lighting is so formidable an affair that it needs constant skilled supervision. The Association proposes to do the work of consulting engineers, and points out the advantage of tenders to a standard specification, as though it were something new. It is promised that members are to be "relieved from any expense (for the usual extras) beyond that specified in the original estimate." Inspection of boilers, engines, accumulators, and surveying of risks "for the fire insurance companies" is, after this, easy work. Among the many suggestions that electric lighting is a troublesome if not dangerous matter, unless periodically inspected by this new Association, we find, "such inspections are very necessary, as in the course of years experience shows that the original number of lamps is increased, and the mains becoming overloaded, heating is liable to ensue."

TELEGRAPHIC ADDRESSES.—Mr. H. Sell has just issued the first of the Quarterly Supplements to the 1894 edition of Sell's "Directory of Registered Telegraphic Addresses." The supplement is free to subscribers to the book.

CONRADY'S AUTOMATIC REGULATOR.—We have received from Messrs. Eugen Conrady and Co. a circular giving particulars of their automatic regulator for dynamo-electric machines, for which it is claimed that the work required is done automatically, and with promptness and accuracy. The regulator consists of a suitably wound solenoid, the core of which operates a reversing friction-clutch to which power is supplied mechanically. The solenoid has, therefore, no other work to do but to put the friction-clutch into or out of gear, and thus absorbs only a negligible amount of electricity (from 5 to 30 watts). The power required for operating the regulating being supplied from a separate source, may be made of any required amount without interfering with the prompt and accurate action of the regulator. The regulator may be adapted to operate either a variable resistance, or the brushholder of a series dynamo, or the throttle-valve or expansion gear of the steam or other motor driving the dynamo, &c. The regulator is made suitable to control electric supply systems of any kind, and it is claimed that the regulator will keep dynamos controlled by them within 1 per cent. of the required normal condition (current or voltage). In cases where variations of the speed or of the load of a dynamo cause appreciable variations of the E.M.F., the regulator will pay for itself in a very short time. The London agents for Messrs. Conrady's specialties are the Indestructible Ignition Tube Syndicate (Limited), 100c, Queen Victoria-street, E.C.

MEDICAL BATTERY COMPANY.—An application has been made before Mr. Justice Williams, in which the receiver in this Company (now in liquidation) asked for leave to continue the business for another two months, and to sell "electric" belts and appliances, the grounds of the application being that at the date of the stoppage of the business operations there was in hand a considerable stock of appliances, estimated to be worth about £6,000. In support of the receiver's application counsel argued that the belts and appliances were of "some curative value." A continuance order has been granted for a further period of two months, to ensure a more complete realisation of the Company's assets.

UNITED ELECTRIC WIRE COMPANY.—We are informed that Mr. T. Collingwood has retired from this firm, which is now being carried on under the management of Mr. F. H. Berry.

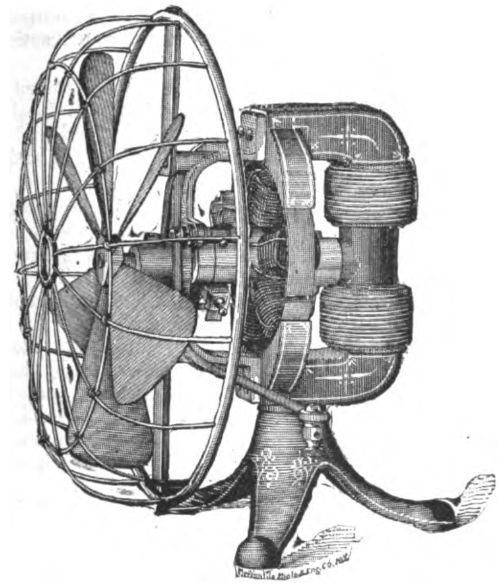
SELF LUBRICATING BEARING.—Mr. W. Farrar forwards a circular illustrating and giving particulars of Broughton's self-lubricating bearing, which it is claimed is specially suitable for dynamos, motors, &c. Several of these bearings have been running in Leeds for some months, and have, it is stated, given every satisfaction.

STRAKER'S OIL BEARING.—In reference to a Trade Note appearing in our last issue, we are asked to state that Mr. C. S. Northcote, in conjunction with Messrs. B. Verity and Sons, have taken up an agency for this oil-bearing at their Manchester offices.

ELECTRIC COOKING AND HEATING.—A Novelties Exhibition has been held in Bath during the past fortnight, at which one of the chief attractions has been the electrical displays, which have been carried out under the supervision of Mr. G. F. Metzger, of the Bath Electric Lighting Company. It is generally thought that much of the success of the Exhibition is due to the electrical installation.

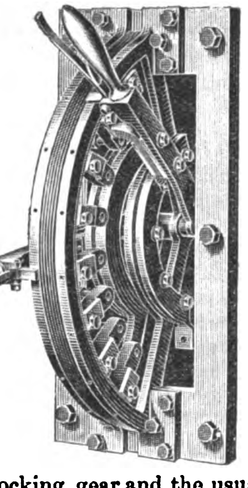
Digitized by Google

GENERAL ELECTRIC COMPANY.—We have received from this Company a new edition of their electric bell catalogue, which contains particulars and prices of a number of new articles. The Holden repeaters for electric bells have been modified, and are now offered to the trade. A large number of pushes, some made entirely of china, and front door pulls are illustrated. Amongst



other items dealt with in the catalogue are electric gas lighters, including spare parts for repairs, Edison-Lalande batteries, small motors, &c. The illustration shows a motor attached to a fan, but which would no doubt be useful for experimental and other purposes.

MESSRS. NALDER BROS.—On a recent visit to Red Lion-street, Clerkenwell, we saw a new form of battery switch, designed to occupy a minimum amount of wall space. This switch is made to carry 200 amperes, has eight pairs of contacts, but occupies only 10½in. by 1ft. 11in. space. The handles project 1ft. 4in. from the wall



in their mid-position. Locking gear and the usual resistance coils are provided, and the contacts are all adjustable for wear. We were surprised to find that this firm have a dozen "secohmmeters" in hand, and that these are practically used by manufacturers. A large "Anthony" bridge had just been completed, and is, we understand, destined for an American university.

BIRMINGHAM.—The Empire Palace was opened on Monday last, and is considered one of the handsomest buildings in the town. The electric light and telephone is installed throughout the building, the telephone in substitution of electric bells.

BRADFORD.—At the last meeting of the Town Council Alderman Moulson, Chairman of the Gas and Electricity Supply Committee, presented the minutes of the Committee recommending that a circular be issued to the residents of the districts of Frizinghall, Manningham, and Heaton, in order to ascertain their wishes in regard to the electric light supply, and authorising the electrical engineer to prepare an estimate of the cost of the suggested works, and further to circularise the residents of several of the large thoroughfares as to the support they were prepared to give to the Corporation scheme for extending the electric lighting area. After a brief discussion the minutes were adopted.

BREWERY LIGHTING.—The Chesterfield Brewery Company some time back placed an order with Messrs. Laing, Wharton and Down, of New Bond-street, London, for an extensive electric lighting plant for lighting their premises and cellaring at Chesterfield and the adjoining Station Hotel, of which they are the proprietors. The work has now been completed, and is considered a great success. The installation includes a battery of 56 cells. A special feature of the lights is an examining light for inspecting the barrels, which is peculiarly necessary in brewery lighting. This consists of a long thin-rod, inserted in the end of which is a small incandescent lamp enclosed to prevent breakage. This is thrust through the bung-hole of the barrel and enables the interior to be thoroughly inspected.

BRISTOL.—Complaints are being generally made against the charges for gas during the past year. It appears that the Sanitary Authority are charged, within a small amount, the same as before the introduction of the electric light, whereas a member of the Authority pointed out at the last meeting that a saving of some millions of cubic feet of gas had been effected. As private consumers have also complained of the amount of their gas bills, it is felt that something must be radically wrong somewhere. A written report is to be presented on the subject, which may prove interesting.

BURTON.—The Finance Committee of the Town Council have agreed that application shall be made to the Local Government Board for permission to borrow £55,771 for works in connection with their sewerage and electric lighting schemes.

BURY.—The Town Council have approved the plans for the scheme of electric lighting which has been adopted for the Borough, and for which it was resolved at the last meeting to apply for powers to borrow £25,000.

BUXTON.—A special meeting of the Local Board has been held to consider the electric lighting question. After some discussion it was proposed that a competent consulting engineer should be appointed, but the Chairman of the Board, Mr. C. F. Barnard, pointed out that the town had several important undertakings in hand, and if they adopted an electric lighting scheme, the rates would have to be increased. It was suggested that they should wait until several loans fell in in 1902 before any fresh important undertakings were contemplated by the town. Ultimately the Chairman's views prevailed.

CHISWICK.—The Clerk to the Local Board has received from the Board of Trade amended regulations regarding the supply of electric light in Chiswick, to which no exception has been taken by the Board. The Surveyor announced that the boilers were completed, and the engines would soon be ready. Plans are to be deposited next week.

CHURCH LIGHTING.—Mr. T. Harding Churton, of Leeds, has secured the contract for lighting the Great Synagogue at Belgrave-street, for which nearly 80 incandescents of various candle-power will be required.

COUNTRY HOUSE LIGHTING.—Storrs Hall, Windermere, has just been lighted throughout by electricity, 120 16-c.p. incandescents being distributed over the various rooms. The current is at present obtained from an electric launch owned by Mr. L. Parsons, by whom the installation has been carried out; but ultimately a complete plant is to be put down, including a battery of 52 E.P.S. cells.

DERBY.—At a quarterly meeting of the Town Council, just held, a question was addressed to Mr. Marsden regarding the electric light installation. In reply, Mr. Marsden stated that for business reasons he would prefer not to give any definite figures as to the expenditure or receipts in connection with the electric lighting scheme, but the success of the installation had exceeded their most sanguine expectations. The applications for current had been much larger than were at any time anticipated. More money would shortly be required, but not for laying down further plant, of which they had an ample supply. The money would be required for the supplying of fixtures and fittings to customers, and the more money the Committee expended upon such fixtures and fittings, the greater success would the scheme ultimately become.—— The Electrical Exhibition at the Mechanics Institute, Wardwick, Derby, is to be opened on May 14th, by the Mayor.

DUBLIN.—A rumour was spread that Captain Purcell had suggested that the recent disastrous fire upon the premises of Messrs. Arnot and Co., might possibly have been caused by the fusing of electric light wires. Captain Purcell has denied that such a statement had been made by him, and Mr. M. Ruddle, electrical superintendent at the central station, Fleet-street, Dublin, is anxious that such a report should be contradicted promptly. Mr. Ruddle explains that the electric lighting of Messrs. Arnot and Co's premises was all in order on the morning of the fire, and that at 2 p.m. it was found that the gas from a broken 3in. gas service was burning among the fallen ruins close to the electric lighting mains, and, solely as a matter of precaution, it was deemed advisable to disconnect the wires at this point, the disconnection only affecting three consumers on the system.

GLASGOW.—The *Evening Citizen* has recently got together some statistics as to the popularity of electric lighting in Glasgow, and, in a recent issue states that during 1893 the production of the

Digitized by Google

electric current has been rapidly increasing. At the present date no less than 242 shops, 21 warehouses, 91 offices, 3 churches, 13 clubs, hotels and theatres, and 12 private houses, are using the electric light, and apparently to the general satisfaction of the users except in the matter of cost. Complaint is generally made that the charge of 7d. per unit is prohibitive to the more general use of the electric current.

GUILDFORD.—In regard to the dispute between the Guildford Town Council and the owners of the Electric Lighting Provisional Order for Guildford, the Board of Trade have suggested that a clause be inserted in the Provisional Order under which the Local Authority will have power to purchase the undertaking within six months after the expiration of 35 years from the commencement of the Order.

HEATH TOWN (WOLVERHAMPTON).—The Local Board have recently been in communication with the Parliamentary Agents as to the probable cost of obtaining an electric lighting Provisional Order and subsequent confirmation. After hearing the replies it was stated that the proper course was to consult an electrical engineer to advise the Board as to the proper steps to be taken to obtain an Order.

HULL.—Mr. Councillor Holder, Chairman of the Electric Lighting Committee, at the last meeting of the Town Council, gave a short account of the progress made during the past year with the electric lighting scheme. He pointed out that when the scheme was first broached, nothing but failure was predicted. He believed their critics were sincere in their fears, and would now be the first to rejoice at the unqualified success of the electric light undertaking, both from the points of view of illumination and finance. As an illuminant they had never had a single accident or flicker from their station, and as a commercial venture it would be seen by the balance-sheet that they had expended £1,631 to produce £2,519. They had paid working costs and up-keep, and had a balance of £888 to pay off the interest on £25,000 of capital. The interest absorbed £750, and left them with £138 towards the sinking fund. It had proved additionally profitable to the borough from the fact that they had borrowed from the Borough Fund surplus at 3 per cent., or ½ per cent. more than would have been received through the bank, and thus had enriched the town to the extent of £125. In the past year the progress made was shown by the fact that in the March quarter there were only 42 users of the electric current, whereas in December there were 148. In March 3,790 lamps were connected; in December, 8,036; and arc lighting had increased in a similarly satisfactory ratio. Up to December last they had delivered to consumers 74,600 units of electric current. The Council's engineers might, he thought, fairly be congratulated on possessing a station second to none in the Kingdom, however long they may have been in existence. Mr. Gibbings, the electrical engineer, had estimated that to cover the expenses for the current year it would be necessary to have an income of £4,388, which would require the sale of 162,000 units at 6½d. per unit, the price which they proposed to ask the Council to reduce it as from September next. They were sanguine that they would be able to sell this large number of units, and based their estimate upon the fact that they had sold with only 76 users in eleven and a-half months 74,600 units, whereas at the beginning of this year they had 148 users, which should give them the amount of support necessary to reach the extended total. In the first quarter of the year they had sold no less than 45,862 units towards their 162,000. They had, of course, the two summer quarters before them, but he felt sure that their estimated increase would be reached. As matters stood they were likely to lose slightly on their charge of 6½d. per unit, and they were, therefore, not justified in making any further reduction. Notwithstanding the undoubted success which Mr. Holder was able to show, there were not wanting members of the Corporation who looked askance at the enterprise, and this opposition culminated in an amendment referring back a portion of the committee's minutes for further consideration, but after some further discussion, the amendment was put to the vote, and lost by a majority of 25, and the committee's report was confirmed.

JOHANNESBURG.—Mr. J. Hubert Davies recently entertained a number of the residents to celebrate the inauguration of the electric lighting plant at the Crown Reef, which has been put down at a cost of about £10,000. Mr. Davies pointed out that the inception of the electric-lighting scheme was due to Mr. Jennings. An electrical plant under the conditions which prevailed at the Crown Reef was much more economical than a steam plant, and in the case of this mine all the working machinery either in the mine or on the surface (except the hauling gear) was driven from one generating point. Some of the machinery is a mile away from the motive power working it. The motive power would also have been worked by electricity, but for the fact that they already had an elaborate steam plant working it. Beyond the motive power, the electrical plant provided the lighting, which was equal to 1,000 16-c.p. lamps. Mr. Davies expressed his opinion that so economically could an electrical plant be worked, that several low-grade mines could be governed from one central station with satisfactory results, especially where water could be utilised as the motive power. Mr. Tudhope, in complimenting Mr. Davies, Mr. Jennings, Mr. Irvine, and Mr. Webber, and the staff generally on the result of their labours, said that the day would shortly come when low-grade properties, worked by electricity, would add 50 per cent. to the gold output of the Transvaal, and he looked forward to the ultimate utilisation of the Crocodile river as water-power.

LLANDUDNO.—It is stated that a committee of the Board of Commissioners has decided to oppose the formation of a local electric lighting company at Llandudno, which Mr. W. Kingsland and Mr. R. Bellis are promoting. The Committee's report will be discussed at the next monthly meeting of the Board.

LAUNCESTON (TASMANIA).—In response to the application for tenders for lighting this city by electricity, only two offers have been received complying with the conditions laid down by the City Council, and the tender of Messrs. Siemens Brothers and Co. (Limited), for £32,021, has been recommended for acceptance, as against the tender of Messrs. Henley for £28,615. At a public meeting held to discuss these tenders a resolution was moved that the specifications and conditions had been drawn up by the Council so as to exclude any English and American firms from tendering, and that the better course would be to call for fresh tenders, these to be referred to a Board of three accredited electrical engineers to adjudicate and advise the Council. This was carried, and it was ordered that copies should be sent to the City Council.

MANCHESTER.—The Electric Lighting Committee of the Corporation of Manchester have recently placed an order with Messrs. Mather and Platt (Limited), of Salford Iron Works, Manchester, for two "Edison Hopkinson" dynamos, each of 400 H.P. The machines are to be similar to the two machines already supplied by this firm, having an output of 410 volts 590 amperes at a speed of 400 revolutions per minute, and are intended to work upon the feeders of the 5-wire system. The committee have had so many applications for electric light that their present plant is fully loaded, and an extension is necessary before next season. These new dynamos are to be worked by "Galloway" engines, similar to those already supplied.

MERSEY DOCKS AND HARBOUR BOARD.—At their meeting this week the Board will decide as to the construction of a jetty at the south-east side of the Duke-street bridge, East Float, Birkenhead, to be provided with hydraulic cranes, and to be lighted throughout by electricity, the total sum to be spent being £7,500.

NEW ROYAL COLLEGE OF MUSIC.—This college, which was opened last week by the Prince of Wales, is lighted throughout by electricity, the installation having been fitted up by Messrs. Thompson and Ritchie. The organs are worked by electric motors fitted up by Messrs. Bergtheil and Young. A novel feature in the building, and which should prove extremely convenient, is the connecting of each of the nearly 100 class-rooms by telephone with the administrative offices and with the private room of the Director.

NORTHUMBERLAND.—The Committee of Visitors of the County Lunatic Asylum have presented their report, in which it is stated that the Visitors have carefully considered the question of adding to the existing gas works, or, as an alternative, the erection of electric lighting works capable of supplying the electric light to the asylum and the steam power required for the new laundry. The estimated cost, including superintendence during construction of the works, shows a total of £7,275, against an estimate for the extension of the gas works of £5,060. After consideration the Committee submit to the Northumberland County Council both schemes, but are in favour of adopting the electric light, and recommend it to the consideration of the County Council, subject to the approval of Commissioners in Lunacy and the Secretary of State.

POPLAR (London).—The District Board of Works have considered the report on the electric lighting of the district recently presented by Mr. Preece, in which it will be remembered that he strongly advises the Board to take into its own hands the lighting of the district for which the necessary Provisional Order has been obtained, and after discussion it was decided to refer the matter to the Works Committee for their consideration and report.

PLYMOUTH.—The Bill promoted by the Plymouth and Stonehouse Gas Company, authorising them to raise additional capital and to apply for a Provisional Order under the Electric Lighting Acts, was discussed before a Committee of the House of Commons this week. In support of the Company's application, it was pointed out that the Plymouth Company charges less for gas than any other company in the country, viz., 1s. 9d. per 1,000, against no less than 3s. 1d. by the leading London Company, in fact, gas was cheaper at Plymouth than at Newcastle.

PROVISIONAL ORDERS.—The Provisional Orders promoted by the Buxton Local Board, the Corporations of Chesterfield, Peterborough, and West Hartlepool, came before the Examiner of the House of Commons, on Tuesday, for proof of compliance with standing orders. In each case it was decided that the standing

Digitized by Google

orders had been complied with, and the Bills will be reported for second reading in due course.

THE ROYAL ACADEMY.—Special reference was made at the recent Academy banquet to the effectiveness of the electric lighting installation in the galleries, and we are asked to state that the work was carried out by Messrs. Belshaw and Co., of Victoria-street, S.W.

RUGBY.—A deputation of the Rugby Town and Trade Improvement Association recently waited upon the Local Board, asking their assistance to provide the necessary number of subscribers to enable an arrangement to be entered into with the National Telephone Company for opening trunk communication with Rugby. The Board decided to take the suggestion into consideration.

ST. LUKE'S (LONDON).—In reference to the notices recently served by the County of London and Brush Provincial Electric Lighting Company, intimating their intention to commence the laying of electric lighting mains in the parish, the Parliamentary Committee of the St. Luke's Vestry have decided to take expert opinion as to whether the Order obtained by the Company is effective, in view of the fact that its terms have not been observed by the Company. A recommendation that the Company should be notified of the proposed action of the Vestry has been referred to a sub-committee, to consider and investigate the whole subject of the Electric Lighting Order.

ST. PANCRAS.—The Guardians have recently discussed the question of adopting the electric light at the workhouse and have referred the matter to the Finance Committee for their report, and the Baths Committee have been requested to take into consideration the question of lighting the baths by electricity.

SHEFFIELD.—The electric light has recently been installed throughout the Sheffield Library, and at the annual meeting held last week it was stated that the light had proved a complete success, to the gratification of all concerned.

SHIRLEY AND FREEMANTLE.—The Local Board have referred a letter from the Electric Construction Company to a special committee, and after discussing a report from the General Purposes Committee on the electric lighting subject, have appointed a sub-committee to investigate the whole question of lighting the district by electricity.

SHOREDITCH (LONDON).—Owing to the action of the Gas Light and Coke Company in declining to allow discount on the quarterly accounts, the Shoreditch Vestry have decided to push forward their electric lighting scheme with all possible dispatch. The Vestry have notified their opinion that a reduction in the price of gas should have been made before a dividend of 12 per cent. was declared by the gas company.——Messrs. Manlove, Alliott and Co. have reported to the Vestry on the question of dust destructors, and the utilisation of the heat for generating electricity and supplying the baths and wash-houses. In their report they state that, so far as they are aware, the only scheme to be considered as a practical mode of dealing with the question is that invented by Mr. Druitt Halpin. Under the scheme referred to in the report it is estimated the Vestry can make an annual profit of £1,390 by a capital expenditure of £17,500, of which £8,800 is put down for the destructor and £8,700 for the necessary steam generators, pumps, piping, buildings, &c. The estimated revenue is £4,290 per annum, at an annual maintenance charge of £2,900.

SOUTHAMPTON.—At the opening of a new emigrants' home it was announced that the electric light would shortly be introduced.

THETFORD.—The clock at St. Peter's is to be lighted by electricity from dusk to 11:30 p.m.

TRAIN LIGHTING.—We are informed that the German Postmaster-General has ordered 42 mail coaches for the night express train service, all of which are to be lighted electrically, and that Boese accumulators have been specified. The gas which is now used in the old coaches is to be replaced by Boese accumulators in all cases where the coaches come in for repair. The Austrian State Railway has also, we understand, adopted the Boese accumulators for train lighting. The International Electric Company, who are the agents for the United Kingdom and the Colonies for the Boese batteries, report that the sale is considerable, and that the demand is steadily increasing.

WORTHING.—Councillor Rafferty, Chairman of the Lighting Committee, and Capt. Fraser, of the Worthing Town Council, visited Brighton last week, and were conducted over the central station by the Mayor, Alderman Moon, and Mr. Wright, the superintendent of the works. Worthing is contemplating the introduction of the electric light on a system similar to that in use at Brighton.

ANNUAL SUPPER.—A party, numbering about 50, of Edinburgh electricians, held their annual supper at the Prince of Wales's Hotel last week, under the presidency of Mr. O. Cox-Walker. It having been mutually agreed that there was a good time coming for the Edinburgh electricians, the rest of the evening proved of an agreeable character.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

March 31, 1894.

6,458. S. Z. DE FERRANTI. London. Improvements in dynamo-electric machines.

6,482. P. MOREAU and J. MUNIER. London. Improvements in, or relating to, multiple telephonic systems and apparatus.*

6,491. S. PITT. London. Improvements in and apparatus for converting electric currents. (A. Blondel and Sautter, Harlé et Cie., France.)*

6,495. E. HERMITE, E. J. PATERSON, and C. F. COOPER. London. A process for protecting iron pipes from corrosion by passage of electrolysed chloride solutions employed as disinfectants.

6,497. E. HERMITE, E. J. PATERSON, and C. F. COOPER. London. Improvements in apparatus for electrolysing chloride solutions employed for disinfecting.

April 2, 1894.

6,512. F. H. ROYCE. Manchester. Improvements in dynamo-electric generators and motors and allied machines.

6,528. F. H. ROYCE. Manchester. Improvements in dynamo-electric generators and motors and allied machines.

6,554. BULLERS (LIMITED) and E. J. CHAMBERS. London. Improvements in or additions to metallic tubular telegraph poles, and metallic tubular poles for other purposes.

April 3, 1894.

6,606. C. A. ALLISON. London. Systems for controlling electric lights. (The Electrical Specialty Company, United States.)*

6,623. P. R. ALLEN. London. Improvements in electric lighting apparatus.

6,649. A. KERSHAW. London. A new or improved mechanical indicator for electric and other bells.

6,661. T. J. RORKE. London. Improvements in electric switches.

6,669. J. C. FULLER, G. FULLER, and W. E. LANGDON. Improvements in porcelain and other insulators.*

April 4, 1894.

6,721. THE NATIONAL TELEPHONE COMPANY (LIMITED) and C. EGGAR. Glasgow. Improvements in apparatus for signalling between police stations and district call-boxes.

6,742. SIEMENS BROTHERS AND CO. (LIMITED) and G. S. GRIMSTON. London. An electrically operated electric switch.*

April 6, 1894.

6,850. W. T. UNGLEY, Jun. Electric lamp protector.

6,883. J. IMRAY. London. Improvements in telegraphic and telephonic apparatus. (La Société anonyme pour la transmission de force par l'électricité. France.)

6,912. The firm of KÖLNER ACCUMULATOREN-WERKE GOTTFRIED HAGEN and C. BEYER. London. Improvements in and relating to moulds for casting grids for the active material of electrical accumulators.

6,917. H. GUTHRIE. London. Improvements in apparatus for electrolytical purposes.

April 7, 1894.

6,937. W. DIXON. Glasgow. An improved method of illuminating by the electric arc.

6,942. D. SINCLAIR. Glasgow. Improvements in "cords" and plugs for telephonic switchboard circuits.

6,947. R. J. GÜLCHER. Liverpool. Improvements in plates or electrodes for accumulators.*

6,975. A. J. SMITH and H. J. WRIGHT. London. Improvements relating to the manufacture of plates or electrodes for electric accumulators, or secondary batteries, and to machinery or apparatus therefor.

April 9, 1894.

7,050. G. C. FRICKER. London. Improvements in electrically illuminated signs.

7,054. E. J. CLUBBE and A. W. SOUTHEY. London. Improvements in electrically propelled vehicles.

April 10, 1894.

7,080. J. OULTON. Bradford. Improvements in phonographs.

7,094. W. J. S. BARBER-STARKEY. Manchester. Improvements in and connected with secondary electric batteries.

7,116. C. BRADBURY. London. Apparatus for calling any desired station on a telegraphic or telephonic line. (F. Trinks, Germany.*)

7,121. W. BIDDLE and P. KENNEDY. London. Improvements in electric car-lighting apparatus.

7,132. H. CARDONNELLE. London. Improvements in microphones.

7,145. S. O. COWPER-COLES and B. W. WALKER, Bart. London. Improvements in, or connected with, the electro-deposition of metals or metallic compounds, and the treatment of deposited metals or compounds.

7,148. N. S. KEITH. London. Governor for electric, water, and other motors.

Digitized by Google

7,155. A. HIGGINS. London. An improved multiple distributing electric cut-out.

7,165. E. J. CLUBBE and A. W. SOUTHEY. London. Improvements in secondary voltaic batteries.

7,176. H. CARBONNELLE. London. Improvements in and relating to telephonic systems.

April 11, 1894.

7,205. A. F. B. GOMESS. London. A new or improved process for the electro-deposition of aluminium and aluminium alloys.

7,206. A. F. B. GOMESS. London. A new or improved process for the electro-deposition of aluminium and aluminium alloys.

7,214. H. V. COAD. London. Improved safety arrangement for electric miners' lamps.

7,215. E. MAGNIN. London. Improvements in electric printing telegraphic apparatus.*

7,216. R. HURST. London. An improvement connected with electric switches.

7,238. Sir C. S. FORBES, Bart. London. Improvements in or relating to electric telephones.

7,239. C. COERPER. London. Improvements in alternating-current electric motors.

7,240. W. C BERSEY. London. Electrically-propelled common road vehicles.

7,244. W. H. AKESTER and H. H. PRICE. London. Improvements in apparatus for electrically-recording circular, longitudinal, or transverse motions of mechanical devices.

April 12, 1894.

7,258. G. BINSWANGER and H. J. COATES. London. Improvements in electric arc lamps.

7,287. S. ROBSON. London. A method of electrically lighting vehicles by their own momentum.

7,311. B. A. N. DOREZ. London. Improvements relating to secondary batteries.

April 13, 1894.

7,402. L. B. TAPPENDEN. London. A new or improved gas or electric light regulating apparatus for railway stations.

April 14, 1894.

7,467. A. J. MARQUAND and E. HANCOCK. London. Improvements in primary, electric, or secondary batteries.

7,468. E. ARNOLD. London. Improved method of, and apparatus for, distributing electrical energy by means of alternating currents.

7,477. H. EDMUNDS. London. Improvements in apparatus and means for vulcanising small articles, more especially intended for vulcanising the insulation at the joints of electric conductors.

7,479. F. J. BEAUMONT and F. HALLOWS. London. An improved electricity meter for registering the amount of current consumed on direct, or alternating, polyphase, triphase, or quadruplephase circuits.

April 16, 1894.

7,530. THE EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED) and J. M. MOFFAT. London. An improvement in electrical glow lamps.

7,539. G. L. DAVIES. London. Improvements in lifting, crane, and hoisting apparatus operated by electrical energy.

April 17, 1894.

7,603. C. J. HAMMERTON. London. Application of electricity to the manufacture of cyanides and ferrocyanides, and improvement in same. Preservation of vessels from corrosion.

7,607. W. DEFRIES and V. J. FEENY. London. Improvements in arc lamps.

7,617. H. B. COX. London. Improvements in thermo-electric generators.*

7,645. J. B. BRAND and C. L. FRANKLYN. London. Improvements in underground conduits for electric railways.*

April 18, 1894.

7,684. W. L. SPENCE. Manchester. Improvements in, or in connection with, electricity meters.

7,688. G. HOOKHAM and S. H. HOLDEN. London. Improvements in, or in connection with, electricity meters.

7,691. C. A. MÜLLER. Bradford. Improvements in the manufacture of carbon rods for electric arc lights. (C. Schmelzer, Germany.)

7,700. J. D. F. ANDREWS. London. Improvements in electric-light ceiling roses.

7,711. W. J. BISHOP. London. An improved arrangement of element board for electro-diagnosis.

7,718. G. G. M. HARDINGHAM. London. Improvements relating to mains for alternate current installations. (The firm of Felten and Guilleaume, Germany.)

April 19, 1894.

7,758. F. TUDSBURY. Sheffield. Improvements in induction electrical machines.

7,801. C. KELLNER. London. Improvements in or relating to electrolytical apparatus.

April 20, 1894.

7,815. T. J. TOMLINSON, Jun., and O. ROBSON. Newcastle-on-Tyne. Improved means for effecting the lighting of velocipedes by electricity.

7,853. W. A. THOMS and W. H. BURGUM. London. An improvement in the electro-deposition of heavy metals with a base metal alloy.

7,865. D. G. F. GERALD and A. W. SOUTHEY. London. Improvements in the construction and working of galvanic batteries.

7,875. F. FRITSCHE. London. A galvanic chain for curative purposes.*

7,879. C. COERPER. London. Improvements in and relating to reflectors for electric arc lamps.*

April 21, 1894.

7,905. R. J. CANAVAN. London. An improved shunt arc lamp.

7,920. J. B. ATHERTON. Liverpool. Improvements in lead sheath cables.

7,933. W. CORIN. London. Portable apparatus for heating by electricity water, milk, or other liquids contained in cups, jugs, or other vessels, and for making tea and other drinks.

7,935. K. O. A. GULSTAD. London. Improvements in electric telegraphy.

7,950. H. GUTHRIE. London. Improvements in apparatus for electrolytical purposes.

7,955. J. H. THOMSON. London. Improvements relating to electric measuring instruments.

April 23, 1894.

7,985. T. DRAKE. Huddersfield. An improved method, means, or process of producing caustic soda and chlorine gas by the electrolysis of common salt in solution.*

7,994. E. DE PASS. London. An improved electrolytic through or cell. (H. Thofehrn, France.)

7,995. H. HIRST. London. Improvements in fittings for electric lamps.

8,007. G. L. ANDERS and W. KOTTGEN. London. An automatic switch for telephones and other electrical apparatus.

8,011. F. JEHL and F. VON HARDTMUTH. London. Improvements in appliances for increasing the duration of the top carbon of electric arc lamp.

April 24, 1894.

8,043. H. B. WYMAN and A. C. GOODWIN. London. An improved insulating cleat for supporting conducting-wires for electrical circuits.*

8,045. W. G. WOOLF. London. Electric bell for application to bicycles, tricycles, and other cycles.

8,061. H. CARMICHAEL. London. Improved apparatus and process for electro-chemical decomposition.*

8,086. W. H. BRADT. Glasgow. An electric alarm for pressure gauges. [Date applied for under Patents, &c. Act, 1883, Sec. 103, November 22nd, 1893, being date of application in the United States.]*

8,115. F. E. ELMORE. London. Improvements in apparatus for the manufacture, electrolytically, of tubes and other articles of circular section.

8,125. H. N. PRENTICE. London. Improvements in dynamo-electric machines and electric motors.

8,149. H. H. LAKE. London. Improvements in electrical measuring instruments. (J. Van Vleck and E. Weston, United States.)*

April 25, 1894.

8,215. J. BIELSKI. London. Automatic current distributor for multiple telegraphic transmission.

8,218. C. S. JONES and H. C. COLLIER. London. Improvements in or connected with electric signalling or communicating apparatus.

8,224. J. G. W. ALDRIDGE. London. Improvements in electric lighting.

April 26, 1894.

8,238. A. B. H. CLARKE. Bristol. Improvements in electro-medical apparatus.

8,240. F. W BALL and J. H. WINTER. Bristol. An improved ceiling rose or suspending electric pendant lamps.

8,273. E. A. CLAREMONT. Manchester. An improved form of shade tilt for electric light flexible-wire pendents or other similar fittings.

8,285. J. W. ROGERS. London. Improvements in arc lamps, especially in the reduction of mechanism.

8,292. J. E. LIARDET. London. Improvements in or relating to the charging of electrical accumulators or secondary batteries.

8,307. J. J. FYFE. London. Improvements in and connected with arc-lamps, and the regulation of the feeding of their carbons.

8,315. W. C. BERSEY. London. Electrically-propelled tramway vehicles.

8,317. H. H. LAKE. London. Improvements in switches for use at central stations of telephone systems. (The Antwerp Telephone and Electrical Works (Société Anonyme), Belgium.)

8,328. G. THRELFALL. London. Improvements in electric condensers. (R. Threlfall, Australia.)

April 27, 1894.

8,343. G. F. SANDERS. Birmingham. An improved globe or shade-holder for electric, gas, or other lamps.

8,350. H. H. LEIGH. London. Improvements in electric batteries. (Vohwinkel, Austria.)

8,376. H. TOMMES and A. WELLNER. Cologne. Water-gauge with electric alarm for steam-boilers, water-towers, and reservoirs.*

8,412. A. FRAZER. London. Improved method of and means for controlling electric currents.

Digitized by Google

April 28, 1894.

8,443. A. Fairley. Blackpool. An improved arrangement of electrical contact surfaces for producing electrical effects in theatres, &c.

8,478. E. J. Clubbe and A. W. Southey. London. Improvements in electrically propelled vehicles.

8,480. T. H. Rushton. London. Improvements in and relating to galvanic batteries.

April 30, 1894.

8,500. H. R. Vereker. Westport. Electrical connector for making insulated joints under water or clay, between cable or other insulated wires.

8,512. A. Wigglesworth. Liverpool. Improvements in and connected with insulators for overhead electrical conductors.

8,525. A. G. Waterhouse. London. A method of overcoming induction on telephone and transmitting lines.

8,534. W. C. Bersey. London. Improvements in electrically-propelled vehicles.

8,539. E. Andreoli. London. Improved telephone and exchange system. (P. E. Raverot and G. A. Hess, France.)

8,552. R. Kersberg. London. Improved commutator brush.*

8,556. E. Stoessel. Liverpool. An improved electrically operated door chain or the like.

May 1, 1894.

8,566. T. Parker. Wolverhampton. Improvements in alternating and multiphase current dynamos.

8,567. W. H. Scott. Norwich. Improvements in brushes and brush-holders for electric generators and motors.

8,585. D. E. Conner. London. Improvements in electric conductors for underground conduits.*

8,587. H. H. Lake. London. Improvements in and relating to electric railways. (W. B. Purvis and M. M. Armstrong, United States.)*

8,599. J. B. McKeown. London. Improvements in electric arc lamps or lighting apparatus.*

8,607. W. P. Thompson. Liverpool. Improvements in or appertaining to electrical exchanges. (A. E. Keith, United States.)*

8,613. W. P. Thompson. Liverpool. Improvements in or appertaining to automatic electrical exchanges. (The Strowger Automatic Telephone Exchange, United States.)*

8,617. T. N. White. London. An electric alarm bag.

8,634. J. C. Fell. London. Improvements in the means for controlling electric lamp circuits from a distance. (R. H. Postlethwaite, New Zealand.)

8,638. S. Pitt. London. Improvements in alternating current, simple or polyphase, dynamo-electric machines. (André Blondel, and Sautter, Harlé et Cie., France.)*

May 2, 1894.

8,654. R. N. Grenville and S. H. Terry. London. Improvements in apparatus used as brackets or chandeliers for electric light.

8,730. T. Froggatt. London. Improvements in, and connected with, supports for electrical batteries used on vehicles and the like.

8,731. T. Froggatt. London. Improvements in electric batteries.

8,733. H. Dawson. London. Improved electrical fire and burglar alarm.

May 3, 1894.

8,761. A. Archibald and G. Tarry. Improvements in and connected with electric fire-alarms.

8,773. F. H. Dennis. Chelmsford. An automatic electric fire-alarm time call.

8,794. P. E. M. Bastion. Birmingham. New or improved electrical appliances, enabling trains in motion to have constant and direct telegraphic communication with the stations or other trains on the same line.

8,795. A Connell. London. An improved holder or support for the receivers of telephones.

8,807. J. S. Gisborne. London. New or improved means for protectn magnetic needles from local attraction.

8 808. R. McL. McDonald and A. McDonald. Glasgow. Improvements in electric batteries.

8,812. Siemens Bros. and Co. (Limited). London. Electrical jacquard apparatus for looms. (Messrs. Siemens and Halske, Germany.)

8,813. Siemens Bros. and Co. (Limited) and W. Dieselhorst. London. Improvements in electric conductors.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d. each.

1893.

6,528. Statter. Dynamo-electric machines, &c.

6,551. Hall. Electrically treating gaseous bodies, &c.

6,751. Placet and Bonnet. Extracting chromium by eletrolysis.

7,711. Schoop. Secondary batteries.

8,567. March. Electric lamps.

8,901. Mercadier and Anizan. Microphones.

10,081. Greenhalgh. Electro-motors.

10,042. King. Secondary batteries.

10,134. Sayers and others. Dynamo-electric machines.

10,142. Fritsche. Electric generators, motors, &c.

10304. Lobley. Lighting and extinguishing electric lamps.

10,584. Castner. Electrolytic apparatus.

10,942. Walker and Wilkins. Primary voltaic batteries.

11,122. Peyrusson. Secondary batteries.

11,176. Gent and others. Electric bell, &c., indicators.

11,384. Raworth. Electric generators.

11,728. Moy. Electric switches.

11,759. Turnbull. Electric bells.

11,973. Siemens Bros. and Co. (Limited) and Obach. Electrolysis of waters.

12,011. Brown. Electric alarm for steam boilers.

12,141. Tyer. Electrical switches.

12,458. Hutin and Leblanc. Dynamo electric machines.

14,469. Richardson. Electric arc lamps.

15,715. Little, W. G. and C. W. G. Distribution of electricity.

20,381. Claremont. Electric-light fittings.

20,816. Keithley. Connectors for electric conductors.

22,863. Lake. (Thomson-Houston International Electric Company.) Dynamo-electric machines, &c.

23,881. Thompson. (Coffin.) Heating metals electrically.

24,271. Bonnard and Piat. Telephonic apparatus.

24,274. Kellner. Electrolytical decomposition of metallic salts.

24,517. Mockler. Advertising reflector for electric light globes.

24,864. Thomson. Dynamo-electric machines.

24,911. Dewees. Electric cables.

1894.

3,045. Bäärnhielm and Jernander. Electric insulating compound.

3,111. Haddan. (Williams.) Electric signalling devices.

3,275. Chester and Rathbone. Arc lamps.

3,730. Claremont. Electric arc lamps.

3,902. Chamberlain and Hookham. Applying electro-motors to lathe work.

3729. Claremont. Dynamo electric machines.

3,749. Boult. (Cudell and others.) Galvanic batteries.

3,986. Thompson. (Ries Electric Specialty Company.) Electric motors.

4,083. Schleyder. Electric arc-lamps.

4,539 Dieselhorst and others. Joint for wires and electrical conductors.

5,118. Heys. (Heilmann.) Electro-locomotion on railways.

5,243. Lewis. Electric perforating pens.

COMPANIES' MEETINGS AND REPORTS.

West India and Panama Telegraph Company (Limited).

The thirty-fourth ordinary general meeting of this Company was held on Wednesday at Winchester House, Mr. C. W. Earle (Chairman) presiding.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting and the minutes of the previous meeting, which were confirmed.

The CHAIRMAN: I suppose you will take the report as read? It is one that deals with an uneventful period in our history, and the advantage of such a condition of things is that it limits the material of my address to you, and consequently my occupation of your time. On the accounts, under the heads of Abstracts A and B, I have very little to remark, but, of course, I shall be happy to answer any question any shareholder may put to me upon them. The figures fluctuate within very narrow limits according to the incidents which more or less affect the business we carry on. The outcome of the accounts may be summed up in this way. We have received £4,093 less than in the corresponding period of last year, and our expenses are £2,553 less, the net result being that we are £1,540 worse off than we were at this time last year. Well, now, it is very natural that some shareholders should ask, How is it that as you are £1,540 worse off than in 1893 you can afford to pay us an extra 3d. dividend? Because at this time last year we only recommended a dividend of 6d. That is to be explained by the provisions we were enabled to make in the first six months of 1893. During that period we had what I might describe as a windfall. For some seven weeks there was an interruption in the French cable between Hayti and Cuba, and the consequence was that our competitor's international traffic, such as it was, passed over our line between Martinique and Cuba instead of going over theirs, giving us about £2,800. With the help of that addition to our receipts we were enabled to contribute £3,000 to our reserve fund, and to carry forward a considerable amount for us, namely, £4,000. In the present half-year, four months having elapsed, we are enabled to estimate what the probable outcome of the half-year will be, and looking to the saving that we shall make from our second ship being laid by in dock at home and so costing us about £200, instead of at least £4,000 a half-year if at sea, we think we shall be able to keep up the dividend for the current half-year to the amount it was before. In looking at the traffics, which are very disappointing, I must caution you not to regard with too gloomy a view the falling off shown in our last published traffic receipts, because the French cable interruption last year

Digitized by Google

lasted from April 19th to June 5th, and therefore in comparing June 6th traffics, this fact must be allowed for. The most important part of our report refers to those raffic receipts which show a very sad reduction, and we have been trying to find out what are the causes. Well, no doubt trade is bad for one thing, and all the telegraph companies are suffering from declines in their traffics. As sugar is the great staple of the West Indies, it is interesting to see what are the prices of sugar now compared with the prices at this time last year. I find that the prices of muscovado, one of the principal qualities, are now from 10s. 9d. to 11s. 9d., against 14s. 9d. to 15s. per cwt. in 1893, and beetroot 11s. 9d., against 18s. 6d. These figures show a very serious falling off in the prices of the principal export of the West Indies, and no doubt it influences our traffic receipts. But then there are other causes, and one of the most striking is the perfection to which the telegraphing public have brought their codes. In 1874, 20 years ago, the average number of words per message was 15·94, say 16 words, whereas it is now 7·31. That is to say, the West Indian merchant, quite irrespective of reductions in tariff, is spending for the same amount of business, just one-half of his outlay in the olden days. Then, the losses that we have suffered from reductions we were obliged to make in 1891 are rather serious. They amount to £8,000 a year, and we estimate that £20,863 has been lost to us in the 2½ years which have elapsed since those reductions were made. In recent years the reductions have been as follows:—In 1889 the connecting companies reduced their tariffs 10½d. a word, and in 1891 we reduced the tariff to some of the more distant colonies 1s. 11½d. a word, and yet we cannot trace a single additional word having been sent, as the result of those reductions. That might be regarded as the normal consequence of reductions in countries like the West Indies, where the only people who use the telegraph are the commercial men and the official class. The bulk of the population would no more want to send a telegram, even if the charge were only a halfpenny, than to go up in a balloon. They do not want to telegraph, and nothing will tempt them. The immediate consequence of our reductions, or at least what followed, was that some of the colonies reduced their subsidies. After making them a present of £8,000 a year, they reduced their subsidies by £3,300 a year. It appears to me that the reason for their doing so was simply the necessity of bringing about an equilibrium in their Budget. I think the Chancellor of the Exchequer in England would be very glad if he could bring about such an equilibrium by appropriating the revenue of an institution which has no votes in the country, and squaring his receipts and expenditure in that way. Well, gentlemen, I do not think there is anything more that occurs to me to say to you. I shall be glad, as I said before, to answer any question, and in the meantime I will propose the following resolution:—

"*That the Directors' report and accounts for December 31, 1893, submitted to this meeting, be and the same are hereby received and adopted, and that, as recommended by the Board, dividends of 6s. per share on the First Preference shares, 6s. per share on the Second Preference shares, and 9d. per share on the Ordinary shares, the last free of income-tax, be and the same are hereby declared.*"

Mr. GERALD W. BALFOUR, M.P., seconded the motion.

Mr. DYET thought some of the expenses for stationery and printing, as well as the general expenses, might be reduced.

Mr. WEDGWOOD inquired, as the reductions of the tariff seemed to have failed to bring more traffic, if it would not be the best policy to raise the rates?

Mr. JAMESON wished to express his satisfaction with the report generally, and with the efforts the Board were making to bring about some satisfactory results in the Company. He should like to know, however, if it would not be possible to do their repairing with one ship instead of two.

A SHAREHOLDER asked what the present total subsidies amounted to per annum?

The CHAIRMAN: £18,900.

Mr. W. GRIFFITH said of course it was a question of policy whether they could return to the old tariffs. They would be justified in doing so, but it was a question which must be to some extent left to the discretion of the Board. But whether they took that step or not, he thought it might be wise to present a memorial to those Governments who had reduced their subsidies, telling them that their business had not increased, and that they did not get a fair return for the capital invested.

Mr. RICHARD CHAMBERLAIN asked if they were exposed now to the full competition which might be expected from the French cables, or must they look forward to something worse?

The CHAIRMAN: I do not think there is anything worse to come from them. As to the criticisms upon the stationery, I do not know whether Mr. Dyet has had any experience of working telegraphic stations or whether he has taken any trouble to compare our accounts with those of other similar companies. I can assure him, not only upon stationery, but upon every other item, they bear most favourable comparison with other companies' accounts, and show that the closest economy is exercised. We have 21 stations which we have to supply with message forms, papers for correspondence, the forms for publication of news which we are obliged to give for nothing. The stationery is supplied by contract, and I do not think it could be obtained cheaper. The same may be said of the general expenses. Every item is looked into. There is no better staff than ours in the City of London, and everything is closely watched by them and the Board. As to raising the tariff, we should be glad to do so, but it is difficult under present circumstances. With regard to the questions about the two vessels, I think I stated in my address to you that our future expenditure on this ship, the "Duchess of Marlborough," was calculated at something under £400 a year. The previous six months had been an exceptional time, as the vessel had to go to Sunderland to be repaired and refitted under Lloyds' survey. Of course these were expenses which would not occur again for a long time. We shall not send the second steamer to sea unless serious interruptions occur which one vessel could not manage. You must recollect that not only our traffic ceases when an interruption occurs, but our subsidies cease also. Therefore, we do not think that we could safely leave our property to the protection of one ship only. The "Duchess of Marlborough" is now in the docks at London, and we do not expect she will cost us more than £400 a year. We are obliged to keep two men on board, and there is the insurance to pay and a few other small matters. She is kept ready to proceed to sea in 24 hours. The suggestion that we should present a memorial to the Governments has already been carried out. I hope the shareholders do not suppose that anything we could think of as likely to affect the authorities has been neglected. We addressed one of these Governments the other day, and all the reply we got was that they would consider the matter. That is all we can get, and I am afraid memorials have little effect upon them.

The resolution was then agreed to unanimously.

Mr. W. ANDREWS moved the re-election of the Chairman as a Director. He said that from day to day Mr. Earle was at his post giving them the benefit of his large experience and knowledge of telegraphs.

Mr. H. HOLMES seconded the proposition, which was unanimously agreed to.

The CHAIRMAN: I beg to thank you for the continuation of your confidence. I must also thank my colleague, Mr. Andrews, for the flattering terms in which he has spoken of me. I feel I hardly deserve them, but I will accept them in the spirit in which they are made. Again I beg to thank you all.

Mr. R. CHAMBERLAIN proposed—

"*That Messrs. Deloitte, Dever, Griffiths and Co. be elected auditors of the Company at a remuneration of 40 guineas, and that they be authorised to expend 60 guineas on accountants' charges.*"

Mr. JAMESON seconded the motion, and in doing so took the opportunity of congratulating the Chairman upon the way in which his labours had contributed to improving the position of the Company.

The motion was then adopted.

The CHAIRMAN: That is all the business.

Mr. W. GRIFFITH: We ought not to separate without passing a vote of thanks to the Chairman and his co-Directors and to the staff.

Mr. F. W. CHURCH seconded the proposition, and it was agreed to unanimously.

The CHAIRMAN having acknowledged the compliment, the proceedings terminated.

London Electric Supply Corporation (Limited).

The seventh ordinary general meeting of the shareholders of this Corporation was held at the offices, Adelphi-terrace, Strand, on Wednesday, under the presidency of Mr. James Staats Forbes.

The SECRETARY (Mr. R. Stewart Bain) having read the notice calling the meeting, the report and accounts were taken as read.

The CHAIRMAN, in moving the adoption of the report, first referred to the accounts. The No. 1 statement, showing the position of the share capital, had in no sense altered in the last year. The sum of £555,000 had been paid up out of a total of £1,000,000 of Ordinary shares and £240,250 had been paid up out of a total of £250,000 of Preference capital. There was, therefore, a very large margin of Ordinary capital, and a small amount of unpaid Preference capital. In regard to the loan capital, at their last meeting he dwelt on the position of the Company and the resources they had in their powers to borrow. He on that occasion called their attention to the necessity of raising more capital to the extent of £50,000, and stated that one of the Directors, Lord Wantage, who was their largest shareholder, had agreed to advance £50,000 on mortgage of the Company's undertaking. He stated at the same time that the principal money would become due in three years, and that there must be no misunderstanding as to the character of the mortgage in the event of circumstances at the end of that time making it impossible either to raise new capital or pay off the loan in some way. Since then the further necessities of the Company, resulting from two causes—partly from expansion and partly from breakdowns and rebuilding—had involved the necessity of increasing the loan to £80,000. The loan becomes payable next March, and they were now under the necessity also of devising means of raising some more capital—not a large amount—to enable them to carry on for the next year or two. With regard to their undertaking as a going concern the accounts for the past year revealed this—that although they were not as good as they could have hoped and as might have been reasonably expected, they were a great deal better than they were in the previous year, for whereas the accounts for the year 1892 showed a loss on the working of about £4,000 in round figures, the accounts now submitted showed a profit—a minute one—but still there was no loss. The number of lamps had increased from 46,197 in 1892 to 61,924 on December 31, 1893. That was an increase of 34 per cent., which was tolerably satisfactory, although less satisfactory than it might have been but for the occurrence, in a less acute form, of some of those disturbing causes in the supply of electricity to their customers which had dogged them from the beginning. Their progress even during the past year had shown a marked improvement in remedying those diseases in various parts of the system which made the patient bad in 1892 and in 1893 not so bad, but still not in sound health. It seemed to him that the thing would turn on this—how far they could, by dint of curing these evils, establish a character for continuity and efficiency of supply. They were in a greatly improved position in connection with all the details of their business as compared with their position in 1892, and they were infinitely more secure than they were in 1891. Notwithstanding all their drawbacks, they had had, as he had said,

Digitized by Google

an increase in the number of lamps of 34 per cent. If the payment per lamp had remained normal—if that had not been affected adversely—the results would have been correspondingly good in respect of receipts, which, however, showed an increase of only 6 per cent., the average price of the unit having been materially reduced owing to the competition among the different companies. The average receipt per unit in 1892 was 6·90d., and in 1891 it was 7d., and they would judge what a difference this made when they were dealing with a quantity of about one million of units. Their position would have been greatly different if with an increase of 34 per cent. in the number of their lights the price of them had remained them same. The cutting of the price had made the cost per unit almost the selling price. The effect had been felt all round, even by the Metropolitan, the Westminster, and the St. James Companies. Those companies were happier than the London Company in the sense that they were more developed ; and they were also happier in another sense, that their capacity of development had cost them a vast deal less than the London Company's capacity had cost. Those companies had followed in the wake of the known and had not rushed to the experimental. One of the things that was affecting them even now was that their experiment had not yet been carried out. The real secret of success in the business was the number of lamps, because the fixed charges were the same, whether the number of lamps was small or large, as the cost of production did not materially increase unless the number of the lights largely increased. There was formerly a good deal of speculation as to what a lamp ought to earn, and probably they would remember that the lamps when they contracted for them were £1 per annum. Invention, however, afterwards found out a meter, and they were bound by their Act of Parliament to sell at per meter as soon as a proper and reliable meter could be found. Naturally, their consumers preferred to pay by meter where they had some idea as to what they were paying for. Contracts were now almost entirely gone out of their business. Great care now was also taken in economising the consumption, which had become almost a mechanical proceeding. They had thus had, concurrently with the diminution in the price of the unit, a considerable decrease in the consumption of the unit. These facts were apparent in the returns of all the companies, and it therefore seemed a question whether the cutting of the rates to a point at which they scarcely paid was desirable, and whether the companies would not be driven in their own interests, and with entire justice to the consumer, to take what the law allowed them to take per unit. A cutting rate, coupled with a diminished consumption, would very soon find its level in there being nothing left for the companies. The proportion of house lighting was also increasing, and the average consumption in private houses was much less than in clubs, restaurants, and such places. The fact was that they were working out slowly the elements on which the undertaking was to be conducted for the future. He did not think it was necessary for him to deal with the details of the revenue account, which were set forth in great detail in the statement which had been presented to them. The accounts showed the minute—he might say microscopic—balance on the right side of £172 ; but this £172 must be taken in contrast with the loss shown in the previous balance-sheet of £3,914. The account was thus in round figures about £4,000 better than it was a year ago, although they had had to contend against the adverse incidents to which he had alluded, many of which would not, they believed, recur. They had now gone through nearly four and a-half months of the current year with a remarkable absence of those faults and interruptions which in former years had so adversely affected them. There was one matter which he desired to point out in the accounts, especially when the position of Director *versus* the shareholder was criticised so much, and that was the question of the apportionment in the accounts of charges to capital. This was a thing which they need not blink at all, and it was quite a mistake to do so. During 1893, as in preceding years, they had placed certain charges to capital account, with the entire concurrence of their auditors. While the business was progressing and their minds were engaged in the building up of the Company, some reasonable proportion of the general charges might be properly carried to capital. In the present case they had carried £4,000 to capital, and he for one was prepared to defend this proceeding against all comers, including the Board of Trade auditor if the latter challenged it, on the ground of it being a reasonable proceeding. It should also be remembered that they were under the obligation of keeping their accounts upon a particular model designed and approved by the Board of Trade with the view to a possible contingency—namely, the right by the Local Authority of each area at the end of a term of years, on notice, to take over these properties at their then value. A good many wise heads had been put together, with an absolute indifference as to the question of how far it affected the immediate revenue, but whether it was proper in a company, out of its revenue, to pay amounts of money from year to year, which, on an aggregate of years, would represent a very large capital sum—to the advantage of the gentlemen who, under the Provisional Orders, could eventually come in to purchase up the concern at its then value. He should advise—and no doubt his colleagues would concur in the proposition—that a legitimate appropriation to capital should be insisted upon with their eyes open, with a view to its effect upon the future, and not exclusively on the present. Sir John Pender, at the recent meeting of the Metropolitan Company, stated that the item of management charges would now disappear for the first time from the capital expenditure. For some years that company, like the other companies, had put to capital account a proportion of their general expenses ; but of course, when they began to make a considerable profit the rule might be relaxed. They had spent on capital account in the past year £33,086. As he had said, they were suffering because they started a great experiment, which, however, might even now turn out to be a great success. It had made wonderful strides in the direction of the original idea up to that moment, notwithstanding all their drawbacks, but he desired to give them an illustration and an analysis of their capital account, and certain expenditure connected with it, as compared with the expenditure required consequent upon the expansion of the business. The account was divided into two heads. One was for new machinery—that was to say, all the addition to existing machinery which was consequent upon the expansion of their business. When they had 46,000 lights they had a factor to deal with, but that number had now increased to 62,000 lights. That meant that every new customer had to be provided with a transformer, a switch, and a great variety of machines, which cost money. The necessity of providing for progress required some outlay for mains, dynamos, &c., but this was a matter which one could accept with equanimity because it meant spending money wisely, to provide for future expansion ; but what was extremely disagreeable was when they were obliged to provide a great deal of new machinery, and to spend a good deal of money to replace something which had become obsolete. The effect upon them in the past year of this had been that out of the total expenditure of £33,086, £13,176 had been for replacing obsolete machinery, which, in fact, was in their way, and it was so inefficient that it was better to sacrifice it by replacing it with new machinery than by keeping it going. That was a charge in connection with the founding of the business. One knew that many things became obsolete by the progress of science, and they then had the alternative presented to them, either of abolishing what had become obsolete or replacing it or "sticking in the mud" and making no progress. He rather pointed to this matter with the object of arguing that there was a limit to this kind of loss. They had now got a machine in work, effective for the lighting of 90,000 lamps, and at the present time the number was 65,000. This number they hoped to develop to 90,000, but what they had to take care of was that when they approached 90,000 they did not fall into danger. At present they had a sufficient reserve of force when the lighting was at its fullest development to secure them against breakdowns, but they would get upon very dangerous ground indeed when they got to between 70,000 and 80,000 lights. What they ought to do—and do very quickly—was to spend £12,000 in providing another dynamo, which would not only give them absolute security in the character of reserve, against the possibilities affecting the 90,000 lights, but it would also give them an increased capacity of 25,000 lights. This was rather an interesting point—that, bad as a thing was, and great as the waste was in effete or obsolete things, a very small amount of money added from time to time to what they had got would give them a large increase of security and capacity. They knew that in the area where they were it had not developed at all to the extent of its capacity, and, therefore, instead of searching for new fields of enterprise, they had determined that the proper thing was to cultivate and develop to its proper capacity the field of which they were in possession ; but that could not be done without money. As he had said, Lord Wantage had been good enough to find £50,000 for them on mortgage, and that sum was exhausted. His lordship then found a further £30,000, which was practically exhausted, or would be very shortly. The point was, what was to be done? They had consulted with some of the largest shareholders at a conference that was held before the general meeting, but he regretted to say that they were unable to come to any result. It would be suicidal to think of regarding the position as hopeless, and "to chuck up the sponge," because a comparatively small additional sum was required. Happily they were in the hands of a gentleman who was the largest shareholder and their mortgagee, and he did not think that that gentleman was likely to resort to extremities without affording his partners in the undertaking an opportunity of considering whether they would not attempt the rescue of the affair just at the moment when it had survived all its unknown troubles, when they were appreciated and almost cured, and just at the time when, notwithstanding all that experience, they found that the increase in the number of lamps was proceeding in a very satisfactory ratio. If they went on at the rate of 34 per cent. upon 62,000 they would very soon have got the 90,000 which they could now safely light, and the income of every 10,000 lamps additional would be for the greater part of it absolute profit. All the fixed charges would remain the same, as would also the sunk capital ; it was the mere coal and water involved in the generation of so many more units. A point which was very satisfactory, and to which he desired to refer at the request of a large shareholder, was the transmission of the current from Deptford. The shareholder in question had found abroad the idea that the ruin of the Company had been the enormous amount of current that was lost in the transmission of the current between Deptford and the distributing stations in London. Mr. Edison warned him (the speaker) about this point when he visited Deptford. Mr. Edison said he thought that the idea was a very fine one, but that they would be beaten by their wastage of current in getting it to London. At that time there were no means of determining what amount did come to London, but they now knew exactly how much current went into the mains at Deptford, and how much came out and went into the stations ; and the loss all told was about 5 per cent., and certainly did not exceed 6 per cent. This was extremely satisfactory ; but they had found out something else. The proportion of this loss of 6 per cent. was about equally divided in the current travelling in the mains and the magnetising of the large transformers at the stations. Their great drawback had been not in the magnetising of these large receptacles at the distributing stations, but in the small transformers on the premises of the consumers. This had been a very serious business, and among the items described as new machinery to replace obsolete they had had to take out transformers which were extremely wasteful, in order to put in others which were very economical. The sum of £5,000, had, however been expended in this way in the past year, and they were going on with this outlay. Already by this change the proportion of current sold had increased. If they could sell, as the low-tension companies professed to do, 75 per cent. or 80 per cent. of the current generated, they would be in a very different position, but they were now working in the improved manner he had intimated. He desired to impress upon them that the undertaking was not a hopeless one, to be abandoned in despair. It was, in fact, emerging from darkness into light, and it would be almost a scandal to let it drift for the want of a little more capital. Turning to the report he

Digitized by Google

remarked that in the past three or four years they had insisted on the engineers of the Company—Mr. Ferranti in the first place, and then Mr. D'Alton (Mr. Ferranti's successor) and their friend Dr. Fleming—putting in black and white from year to year their version of how the thing was electrically and mechanically. He desired to impress upon them that £12,000 was absolutely necessary to ensure the continued supply of current for 75,000 or 80,000 lamps the moment they got to that point. They had now reached to 65,000, and, therefore, if the business progressed, as they hoped in the winter months it would in something like the proportion of last year, they would very soon be at danger point, and then, in consequence of a want of reserve, they might find the whole thing stopped for six hours. All outside debts of the Company, excluding the mortgage, were covered by £6,000. They required, as an outside sum, about £30,000 to carry the thing on for two years, including the new generating unit, which would be a source of safety and expansion both. They were a little embarrassed because they had no working capital, and the £30,000 included a little margin in this direction.

The DEPUTY-CHAIRMAN (Major C. B. Waller) seconded the motion.

Mr. BARHAM regarded the report as very unsatisfactory.

Mr. MULLENS doubted whether persons would provide the capital required at such a rate of interest as 5 per cent. They would have to be tempted by a higher rate—say 10 per cent.

After a few remarks from Mr. CHARLES (who thought that under the circumstances the Directors ought to give the Company their services for nothing),

The CHAIRMAN, in reply, said that Mr. Mullens had answered the material point raised by Mr. Barham, namely, that the mortgage referred to was represented by the debentures. They were issued as security for Lord Wantage's advance; they formed a first charge on the undertaking, and were payable in March, 1895, with a right of foreclosure in the event of non-payment. What they had to do between now and March next was to see whether the shareholders could agree to some plan by which a sufficient sum of money would be provided to enable them to get out of the position of being liable to be sold up by the mortgagee. Probably they would not determine that question that day. He had tried to make it clear that the misfortunes of the Company originated in their starting a great experiment, which had so far failed, but that was no reason for throwing the thing away. What they would have to do would be to consider, he supposed, something like the sensible suggestion which had been made by Mr. Mullens. If a sufficient amount of debenture stock were created to pay off Lord Wantage, or a sufficient amount were created on reasonable terms in conjunction with Lord Wantage's mortgage they could probably go on. Negotiations had been on foot with a view of living in amity with the other companies, and those negotiations were pending at the present time.

He then put the resolution, and it was carried. Subsequently he stated that the retiring Directors were Mr. Joseph Pyke and Major Waller. He had frequently had the point in his own mind whether he himself ought not to retire, and he felt that he ought to do so as far as either his comfort or his responsibility went, but he considered that to retire from a thing when it was in trouble was dishonourable. He was, however, quite prepared to retire if the shareholders wished him to, but he would not voluntarily leave the concern so long as he thought he could retrieve a position which he desired them to remember he had had no part in creating. As regarded other members of the Board, they had not deliberately lost the shareholders' money or their own, and it was to be remembered that they owned two-thirds of the whole of the capital.

On the motion of Mr. BARHAM, Mr. Pyke and Major Waller were severally re-elected, as were also the auditors subsequently.

The CHAIRMAN, in acknowledging a vote of thanks, said that no one lamented the Company's misfortunes more than the Directors; and notwithstanding the little adverse criticism to which they had been subjected, and which was natural, they would not be discouraged from pursuing a course which was most likely to retrieve past disasters.

The proceedings then terminated.

The following is the Directors' report above referred to, which only reached us three hours before the time fixed for holding the meeting:—

The reports of Dr. Fleming and the engineer, appended to this report, describe the works that have been carried out during the year, and the general condition of the Company's station and plant. During the short time the new transformers have been in use their greater efficiency has sensibly decreased the loss of current. When the whole of them are installed, a considerable advantage will arise from the increase in the proportion of saleable current to current generated. The other important new works described in the engineer's report have proved beneficial, and have materially increased the efficiency of the system of supply. The increase in the number of lights during the year amounts to about 34 per cent., and but for the general depression of trade this rate of increase, which was most marked in the first half of the year, would doubtless have been greater.

The result of the year's working shows an improvement on previous years, the revenue account showing a small balance to the good, as against a loss of £3,914. 9s. 7d. last year, and this notwithstanding the reduction of the standard charge to 6d. per unit and the severe and continuing competition in the best districts of the Company's area of supply. In view of the growing increase in the use of electricity, and of insuring uninterrupted continuity of supply to consumers, the Board recommend that a new generating unit of 1,250 H.P. be provided as speedily as may be. This, with the necessary apparatus for connecting new customers, will, however, involve a further extension and expenditure of capital. Mr. Francis Ince has retired from the Board. The Directors retiring by rotation are Mr. Joseph Pyke and Major C. B. Waller, who, being eligible, offer themselves for re-election.

Engineer's Report, dated May 1, 1894.

I have the pleasure to report that during the past year the Company's consumers have received a more satisfactory supply of electric energy; the working of the year, as a whole, showing a distinct improvement on all previous years, both with regard to the steadiness of the light, and the continuity of supply. We commenced the year with a connection of 46,197 lights; at the end of the year the number had increased to 61,924. But for the commercial depression and other disturbing causes in the latter half of year, the increase would probably have been greater. Towards the end of the year a new 300-H.P. dynamo was brought into use. This will prove a great advantage in enabling us to deal with our daylight load without starting the larger machines, and in this way a marked economy will be effected. The 10,000-volt trunk mains from Deptford to London, originally fixed to the parapet of the South-Eastern Railway, were removed and laid underground with perfect success during the summer, and without any interference with the continuity of supply. By this important work we are now protected from the accidents from which we suffered so seriously in the past; whilst the annual charges will be considerably decreased, owing to the reduction in the cost of maintenance, and the rental of wayleaves on the railway.

The distributing mains have been carried into the Parish of Chelsea, and further extensions have been made in the Parishes of St. George's, Hanover-square; St. James; St. Martin; St. George-the-Martyr; St. Margaret and St. John; St. Saviour; St. Olave and Newington; amounting in all to 2½ miles, bringing the total length of distributing mains laid to 38 miles. All the Company's mains have worked satisfactorily during the year, and the charges for repairs and maintenance have been lessened.

A filtering plant, capable of dealing with 100,000 gallons of water per day, has recently been erected at Deptford, by which we are now able to use the river water for the boiler supply, and thus to dispense with a great portion of the supply hitherto derived from the Kent Water Works Co. This will result in a saving of from £400 to £500 per annum under present conditions. New house transformers, amounting to 2,442 H.P., were purchased last year; of these, 1,477 H.P. are now in use on the circuits, leaving in stock 965 H.P., which are being put into use as speedily as possible. Owing to the delay of the manufacturers in making delivery, it was not until the last month of the year that this work could be commenced, but from the observations I have taken up to the present time I am able to say that this change will have good economical results. To replace the whole of the old type transformers now in use, a further 1,045 H.P. of the new type will be required. The generating and distributing plant is in good order, and is working to my entire satisfaction.

P. WALTER D'ALTON, Engineer-in-Chief.

Dr. Fleming's Report, dated May 1, 1894.

I have read the report of your engineer and agree with it. The replacement of the old form of house transformers by instruments of newer and more economical type has now proceeded to a considerable extent. The result of this exchange has already made itself evident, as we anticipated it would, in a decreased proportion of loss in distribution. There is every reason to believe that when this exchange is completely effected the gain in economy will show itself to the extent indicated in the report of last year. A careful process of testing each transformer for efficiency before it is employed is now adopted. Methods have also been put into operation during the last year for measuring the total daily output from the generating station, which permit the effect of improvements in the distribution plant to be clearly ascertained. A systematic record is thus obtained of the number of units generated as well as sold.

J. A. FLEMING, M.A., D.Sc., F.R.S.

Western and Brazilian Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ended December 31st last, to be presented at the twenty-seventh ordinary general meeting, to be held at Winchester House, E.C., on Thursday next, the 17th inst., at 12 o'clock:—

The total earnings amount to £80,338. 18s. 3d., as against £86,954. 11s. 2d., showing a decrease of £6,615. 12s. 11d. compared with the half-year to December 31, 1892. The working expenses amount to £35,592. 8s. 10d., as against £37,165. 11s. 5d., a decrease of £1,573. 2s. 7d. Including the amount brought forward from June 30, 1893 (£7,679. 4s. 7d.), and the dividend received upon the shares held in the Platino Company, the balance to the credit of the revenue account is £61,659. 9s., from which has been deducted £12,027 for debenture interest, and £7,073 for the debenture redemption fund, leaving £42,559. 9s., of which £5,000 has been placed to the reserve fund. The Directors now recommend the payment of a dividend of 7s. 6d. per share, free of income-tax on the Ordinary shares, being a dividend of £2. 10s. per cent. for the year, leaving a balance of £1,045. 6s. 6d. to be carried forward. In the case of shares which have been divided into "Preferred" and "Deferred," the 7s. 6d. per share now recommended will be payable to the "Preferred" shareholders, making up the full dividend of £5 per cent. on the Preferred shares for the year 1893.

The shareholders will remember that at the general meeting of the Company, held on May 12, 1892, the Directors reported that they had made an arrangement with the Brazilian Submarine Company, that in consideration of this Company duplicating at once certain sections of the line, the Brazilian Submarine Company guaranteed this Company a payment of £6,000 per annum. This began from June 7, 1892. The Brazilian Submarine Company have raised the contention that under this agreement they have acquired the right to control the tariff of both Companies, for the purpose of meeting competition. This Company was advised by Sir Horace (now Lord Justice) Davey and by other eminent counsel who have been consulted, that the Brazilian Submarine Company has acquired no

Digitized by Google

such right and has no such such power, and that this Company is entitled to deduct she annual sum of £6,000 from the joint purse. Under these circumstances, the Directors have taken credit for this sum in the accounts, and they are advised that the legal proceedings which this Company has been compelled to institute in the matter will, before the next meeting, in all probability be settled. They do not, therefore, propose to deal separately with the amount on the present occasion.

In consequence of the "Viking" having been in commission for a portion of the half-year under review, the full economy to be ultimately realised by the substitution of the new "Norseman" to replace the two ships formerly in commission has not yet been reached. The Directors have not written down the ships laid up, because, looking at the large amounts paid from revenue for capital purposes for the new ship and the loop lines, and the uncertainty as to the sum that may be realised for the disused ships on sale, they think that this matter should remain in suspense until the sale, subject to the requisite adjustment between revenue and capital being then made.

The shareholders are aware that the exceptional state of affairs in Brazil, referred to in the last report, continued until quite recently. The rate of exchange has also been much depressed.

The fourth annual drawing of the "A" and "B" Debentures, amounting to £14,200, have been drawn and have been paid off at par.

The Pacific and European Company's land line, connecting Buenos Ayres with Valparaiso, was opened for traffic on March 19th last.

The retiring Directors are Lord Richard H. Browne and Mr. C. W. Earle, who offer themselves for re-election, as do also the auditors, Messrs. Turquand, Youngs, Bishop and Clarke, and Messrs. Deloitte, Dever, Griffiths and Co.

NEW COMPANIES. STATUTORY RETURNS, &c.

BRITISH ALUMINIUM COMPANY (LIMITED).—This Company was registered on May 7th with a capital of £100,000, in £10 shares, to carry on any business relating to the winning and working of minerals, the production and working of aluminium or sodium and other alloys, and the production, use and sale of electricity and electric power, for lighting, heating, motive power or otherwise.

CALIFORNIAN ELECTRIC POWER AND MINING DEVELOPMENT SYNDICATE (LIMITED).—This Company was registered on April 28th, with a capital of £30,000 in £1 shares, to construct or maintain electric power or lighting works, telegraphic or telephonic systems, lines, cables and works, railways, tramways, and other means of communication, &c., in California and elsewhere.

LANCASHIRE RUBBER COMPANY (LIMITED).—This Company has been registered with a capital of £70,000 in £5 shares, to acquire the business of a rubber manufacturer now carried on by the Lancashire Rubber Company, and to carry on business as manufacturers of and dealers in rubber and rubber goods generally.

CALIFORNIA GAS, WATER, AND ELECTRIC LIGHT COMPANY SYNDICATE (LIMITED).—The annual return of this concern, which has just been filed, states that 1,475 shares out of an nominal capital of £2,000 in £1 shares, has been taken up, the full amount called, and all calls paid.

CAMBRIDGE ELECTRIC SUPPLY COMPANY (LIMITED).—The second annual return of this Company, made up to March 20th, has been filed. 2,775 shares of £10 each, out of a nominal capital of £50,000, were taken up and allotted. On each of these a call of £8 has been made, resulting in the total payment of £22,200.

CHAMBERLAIN AND HOOKHAM (LIMITED).—The annual return of this Company made up to April 25th has been filed. The nominal capital is £100,000, divided into 5,000 "A" shares of £10 each and a similar number of "B" shares of the same denomination, and of these, 1,000 "A" and all the "B" shares have been taken up, the latter being considered as fully paid. Upon the "A" shares a call of £3. 10s. per share has been made, resulting in the payment of £3,500.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION (LIMITED).—According to the annual return of this Company, made up to March 6th, and recently filed, the whole nominal capital, of £150,000, in £5 shares, have been taken up, the full amount called, and the total amount paid.

CHATHAM, ROCHESTER, AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this undertaking, made up to April 3rd, and recently filed, shows that 3,890 shares have been taken up out of a nominal capital of £50,000, in £5 shares. Of these, 1,863 have been issued as fully paid, upon 2,000 the full amount has been called, while upon the remaining 27 shares a call of £2 per share has been made, resulting in the payment of £10,051. 10s., and leaving the sum of £2. 10s. as yet in arrear.

CITY OF BATH ELECTRIC LIGHTING AND ENGINEERING COMPANY (LIMITED).—The third annual return of this Company made up to March 21st, was recently filed. The nominal capital is £60,000, divided into 5,500 ordinary shares of £10 each, and 50 Founders' shares of £100 each. Of these 3,384 of the former, and all of the latter have been allotted, and of these 2,250 Ordinary, and the 50 Founders' shares have been issued as fully paid. Upon the remaining 1,134 Ordinary shares the full amounts have been called and paid.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to June 6, 1893, was not filed until April 9, 1894. Out of a nominal capital of £800,000, in shares of £5 each, 200 shares have been taken up. On each of these a call of £4 has been made, resulting in the payment of £800.

CROSSLEY TELEPHONE COMPANY (LIMITED).—The annaul return of this concern, made up to December 30th, was recently filed. The Company has a nominal capital of £100,000, divided into 5,000 "A," 12,500 "B," and 2,500 "C" shares of £5 each. At the time of compiling the present return, 607 "A," 120 "B," and 350 "C" shares have been subscribed for and allotted, and the full amount called, resulting in the payment of £5,385.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to February 28th, has been filed. The whole nominal capital of £220,000, divided into 16,000 Ordinary and 6,000 Preference shares of £10 each, was taken up, the full amount called, and all calls paid.

DICK, KERR AND CO. (LIMITED).—The annual return, made up to April 12, 1894, and recently filed, states that the whole capital of £160,000, divided into 16,000 ordinary and 16,000 Preference shares of £5 each, has been taken up, and the full amount called and paid on the Preference shares, while the Ordinary were all issued as fully paid.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to April 3rd, was recently filed. The nominal capital is £95,000, divided into 13,000 Ordinary and 6,000 Preference shares of £5 each. 12,931 Ordinary and 6,000 Preference have been taken up, and the full amount called on the latter class, while £4 per share has been called on the Ordinary shares, resulting in the total payment of £81,724. For subsequent capital arrangements, see *The Electrician*, April 20th, p. 705.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The annual return of this Company, made up to February 6th, has recently been filed. 60,710 shares of £20 each, of a nominal capital of £1,300,000, were taken up, and all of these have been issued as fully paid.

CITY NOTES.

AFRICAN TRANSCONTINENTAL TELEGRAPH COMPANY (LIMITED).—The second ordinary general meeting of this Company, which was to be held yesterday at the Company's offices, 19, St. Swithin's-lane, was adjourned till Thursday next, at noon, a quorum of shareholders not being present.——In connection with the alleged conflict between this Company's party and the Portuguese, the Governor-General of Mozambique states that the official advices from the Governor at Tete contain no reference whatever to any hostile action by the English gunboats. The Governor believes the whole story to be a canard, and says that the telegraph line to the frontier is being actively constructed by the Portuguese.

CHINA AND JAPAN TELEPHONE COMPANY (LIMITED).—A meeting of this Company was held on the 2nd inst. The proceedings were formal, the Directors' report and accounts being adopted, and the retiring Directors and Auditors re-elected. The Directors' report showed that the revenue for the year ended December 31st, after charging debenture interest, amounted to £435. 15s. 6d., which was transferred to profit and loss account, which now amounts to £920. 18s. 10d., which was carried forward. The year's working showed a less favourable result than the previous one, although the gross income of the Company in China has further improved. This was due chiefly to the continued decline in the value of the dollar and the consequent increased loss on remittances from China.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended May 6th were £886, as against £793 in the corresponding period of 1893, being an increase of £93. The total receipts for the half-year amount to £16,400, as against £16,154 for the corresponding period of 1893, an increase of £246.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for April, 1894, amounted to £20,000, and from January 1st to April 30, 1894, £83,000. In the corresponding months of 1892 and 1893, the amounts were £82,800 and £84,000 respectively.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—This Company notify that the laying of the second section—viz., between Labuan and Hong Kong—of their alternative Singapore-Hong Kong cable has now been completed and the line opened for traffic.

HASTINGS AND ST. LEONARDS-ON-SEA ELECTRIC LIGHT COMPANY (LIMITED).—This Company announce the issue of shares to the extent of its authorised capital. The working of the Company has assured the payment of dividends on subscribed capital of 5 per cent. in 1890, 7½ per cent. in 1891, 5 per cent. in 1892, and 5 per cent. in 1893. The demand for electric current in the district served by the Company is increasing beyond the Company's power to supply, and it has become absolutely necessary to enlarge the present station, provide additional machinery, mains, and other necessaries. To carry out these extensions £10 shares are issued at par, payable £2. 10s. on application, £2. 10s. on allotment, and the balance in calls of £2s. 10s. each at two months' notice. Applications must be made by the 12th inst. The prospectus says nothing of the amount of the issue, and is, generally, more than usually vague.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—The traffic receipts for the month of April were £1,174.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have ordered £150,000 Five per Cent. Debentures, Nos. 1 to 1,500, of the Telegraph Construction and Maintenance Company (Limited) to be quoted in the Official List. Application has been made to the Committee to appoint a special settling day in and to grant a quotation to a further issue of 8,000 Seven per Cent. Cumulative Preference Shares in Crompton and Co. (Limited).

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended May 4th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,924.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ending April 30th were £2,490, as compared with £3,604 for the corresponding period of last year.

④ THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 835.—Vol. XXXIII. FRIDAY, MAY 18, 1894. PRICE FOURPENCE. Annual Subscription (U.K.), 19/

NOTES.

In our Correspondence column an interesting reply from Dr. Hopkinson to our leading article of last week will be found. His belief that algebraic methods have been useful for discovery more frequently than geometrical, and that the work being once done, it is often easy to cast it into a geometrical form, points to the need for a clearer understanding of the relation of mathematics to engineers. Let mathematicians, by all means, use algebraic methods, but let engineers be provided with something more intelligible. Dr. Hopkinson is perfectly right in thinking that the methods of the calculus are feared and shunned by engineers, and the reason is simply that some have no heads for algebra, and others have not time to keep their algebra in working order. Algebraical mathematics is largely a matter of practice in transformations and recollection of standard forms of differentiation and integration. Some minds are utterly unalgebraical, as some are unmusical. To appreciate, to remember, and to intelligently use an algebraical method is as impossible in some cases as the recollection and humming of a tune. A very considerable proportion of the intelligent and educated public are unable, perhaps happily, to reproduce a single bar of a popular tune with which the rest of the community has been saturated. Cambridge need not, of course, go out of its way to accommodate totally unalgebraical people with geometrical instruction, for such people do not, of course, take up mathematics as a study.

Some one ought and some one must provide engineers who are either constitutionally or by want of practice unalgebraical, with geometrical methods. Dr. Hopkinson himself has made most valuable contributions, and others have from time to time used geometrical methods or have translated their algebraical work into a geometrical form. But we want more than this—we want well-recognised alternative systems. Dr. Hopkinson says that mathematicians should be ambidextrous equally ready with algebra and geometry. Would that they were! We should then have no cause to complain, and if the calculus could be taught geometrically it would be neither feared nor shunned. A very fair proof of our contention that graphic analysis is not recognised, taught, and studied, is the absence of text-books on the subject. A few engineer's tricks for calculating moments of inertia and a book or two on graphic statics, and that is all. We are very glad to find that Dr. Hopkinson takes so liberal a view of the question. If we have misread his interesting Address, and were in error in supposing that algebraical methods were held to be of supreme importance, and that geometry was comparatively ineffectual, others have probably taken the same view, and have been induced to do so by such expressions as "Formulæ must be used," "Here, again, it is difficult to see how the differential equation and its solution can be evaded."

A short time ago we had occasion to comment on the great waste of steam which results from condensation in steam pipes. Mr. Crompton, in his recent Paper, proposes to get rid of this waste by giving the steam some 8 to 10 per cent., or more, of superheat immediately after it leaves the boilers. While admitting that this would more or less completely prevent condensation in the pipes, we cannot see that any increase of economy would take place. Surely, if a certain number of yards of hot pipe radiate a certain number of thermal units per hour, it is immaterial if this heat escape from saturated or from superheated steam. The waste of energy would be as great in the latter as in the former case; indeed, it might be greater, owing to the higher temperature of the pipes. The only advantage would lie in the absence of condensation, thus preventing the carrying of water into the cylinder; but a much more economical plan would be to pass the steam through a separator. The only really efficient way to prevent loss of heat by radiation from the steam pipes is to have them well lagged with non-conducting material, and, if possible, to shut them down at the boiler end whenever they are not in use.

As for the advantage of supplying the engines with superheated steam, we very much doubt if this is necessary in the case of high-speed electric-light engines. Mr. Willans, in his Paper on "Steam Engine Trials," in 1888, showed that the amount of wetness of the exhaust steam of his engine was entirely due to the work done by the steam during expansion in the cylinders; and that the cylinder condensation which took place on admission was immediately followed by total re-evaporation of the condensed steam. This was with an unjacketed engine supplied with saturated steam. Many engineers are alarmed at the occurrence of wetness in exhaust steam, and think that it shows that initial condensation is going on. Very often they ought rather to rejoice, as the wetness shows they are getting their money's worth out of the steam.

The proposal made by Mr. Geipel, during the discussion, to produce superheated steam by wire-drawing 200lb. pressure of

Digitized by Google

boiler steam down to 150lb. pressure in the pipes, does not strike us as being a satisfactory mode of procedure. To begin with, one would be at the expense of raising high-pressure steam in order to throw away 25 per cent. of its pressure in wire-drawing, involving useless expense and risk in the boilers. But the chief objection lies in the fact that the wire drawing would probably not superheat the steam at all, owing to the wetness of the steam; or, if it did superheat it a degree or two, the effect would be completely lost before the steam had gone 10ft. along the steam pipes, on account of the rapid radiation losses which would in any case occur. Superheating by wire-drawing is a very pretty lecture-room paradox. Engineers are inclined to forget that the properties of real steam, as it occurs in a boiler house and engine room, are considerably different from the properties of what we may call "Regnault" steam. The former is always a mixture of steam and water, in spite of its passage through the best form of separator; and it requires only a very small percentage of wetness to prevent superheating, even though the steam may have received as much as 25 per cent. of wire-drawing.

The enforcing of the ten-minute rule in the discussions at the Institution of Electrical Engineers has been attempted at the last few meetings, but the very praiseworthy endeavour to cut down rambling remarks has been frustrated to some extent by the mode in which this attempt has been made. The Chairman has anxiously watched for a suitable moment, when the rambler paused for breath, to ring the bell, and has asked if the meeting desired that the speaker should be longer heard. An uncertain amount of confused noise has been taken for the applause of those who wish for more. Dissent is impossible except by hissing or cries of No! A show of hands would be much better, the vote being given as a simple arithmetical quantity, and the Chairman can estimate the ratio of hands to total members more easily than the absolute value of the energy expended in joules or foot-pounding. An automatic alarum would really be the more dignified signal, for it would save the Chairman the difficult task of chiming in without interrupting a sentence.

The Paper by Mr. Appleyard read at the Physical Society last week dealt with two subjects, the behaviour of dielectrics under pressure, which ought to interest cable men, but will probably fail to do so, and of heterogeneous compounds of gutta-percha and brass filings. The latter present some points of purely scientific interest in connection with oscillatory discharges, but have a practical bearing in connection with the construction of high resistances. Dr. Fleming showed some rods of a mixture of plumbago and clay at the Society of Arts not long ago, and said that they were satisfactory, but nothing more has been heard of them, and instrument makers would, no doubt, like to keep up the idea that nothing but expensive coils of fine wire are suitable for resistances of hundreds or thousands of ohms. Plumbago slides are offered in a deprecating way as good enough for medical men, and cheap pencil-line-on-ground-glass megohms are to be bought. Plumbago and plaster of Paris can be made up into resistances, but what is wanted is some thoroughly trustworthy mixture. Seeing that the temperature coefficient of carbon is negative, while that of metal powder is positive, a negligible coefficient seems attainable.

In our issue of May 26th last year we described the Agthe and Kallmann systems of automatically notifying and localising faults occurring on the huge three-wire network existing in Berlin. Elsewhere in the present issue we give in abstract a Paper recently read before the Elektrotechnischer Verein by Dr. Passavant, in which he has something to say about the actual working of these methods of continuously controlling the insulation of the Berlin system of mains. During the past nine months fourteen faults have in this way been signalled, localised, and at once removed. Dr. Passavant does not tell us anything about false alarms and very little about faults not signalled, but the figures actually given with regard to the latter point show the Agthe and Kallmann devices to be extremely reliable. Out of nine failures that occurred on the main cables five were signalled; of the four unsignalled faults two occurred on circuits not yet provided with signalling apparatus, and two were too small to start the alarm. This record, and the fact that the apparatus has had a year's actual trial in Berlin, will perhaps induce some of our own central station engineers to give the idea a thought. Nowhere does the dictum that prevention is better than cure apply with more force than where interruptions of an electric supply are concerned.

Like the posters that now disfigure so many of our fields and woods, cacophonous cacotechnies, such as the "bega-farads" and "quegohms," to which we made some allusion in a recent leading article, are, fortunately for the continued existence of the Anglo-Saxon idiom, calculated to excite opposition as well as arrest attention. Such, unfortunately, is not the case with the humbler flights of the practical man. It is to his attempts to be at once picturesque and pithy that we owe the monstrous regiment of "boosters" and "buzzers," "naked conductors," and "triple-petticoated insulators." One of the latest admissions to this somewhat mixed society is the "milker," whose useful functions and simple nature were recently set forth in our columns by Mr. Arnot. At first glance the "milker's" relationship, if any, to the other members of the society was difficult of elucidation. We felt satisfied that he could have nothing in common with the boastful "booster," but hazarded the conjecture that he was, perhaps, first cousin to that pink of propriety, the "triple-petticoated insulator," when a brighter brain than ours solved the mystery by dogmatically asserting that a "milker" was obviously only a species of "feeder."

Society of Arts.—The *conversazione* of the Society of Arts is fixed to take place at the Imperial Institute, on Friday evening, June 22nd.

Obituary.—Mr. Arthur Edward Robinson, chief of the Electro-Chemical staff at the Electric Construction Company's works at Bushbury, Wolverhampton, expired, after a brief illness, on Saturday, the 5th inst. Mr. Robinson was only 34 years of age.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	Oct. 25th, 1893.
Bissao-Bolama	Nov. 24th „
Brest-St. Pierre (P.Q. Co.)	Mar. 29th, 1894.

Finsbury Technical College.—A students' conversazione will be held at the Technical College, Finsbury, E.C., on Thursday, May 24th, at 7 p.m. A lecture on "Polarised Light" is to be given by Prof. S. P. Thompson, while Prof. Meldola will describe "The Camera as a Scientific Weapon."

An Electrical Standardising Laboratory for Austria.—It is announced that the State Normal Standards Commission of Austria has decided to establish an electrical laboratory for standardising purposes in connection with the new buildings which are in course of erection for the Commission.

Utilisation of Water Power in Switzerland.—A firm at Aaran has just secured a concession to construct a canal in connection with the Rhine, by which no less than 15,000 H.P. will be made available. It is stated that the large aluminium works at Neuhausen have already contracted for 10,000 H.P.

Electric Radiation.—Our readers will be glad to hear that Prof. Oliver J. Lodge has a treat in store for his audience, at his lecture on "The Work of Hertz," at the Royal Institution, on June 1st. He promises to show a number of interesting, indeed, we may say, rather surprising, experiments on electric radiation.

Bristol.—Recently the Mayor of Bristol, together with the High Sheriff and several other prominent citizens of that ancient city, paid a visit to the Bristol telephone exchange, for the purpose of "inaugurating a new switchboard." We may soon hear of a new station voltmeter being inaugurated by a Prince of the Royal blood.

Electric Power Transmission in Austria.—An electric power transmission plant on the "Drehstrom" system has recently been put down by Messrs. Siemens and Halske, of Berlin, in connection with the Linz Waterworks. The electrical energy is transmitted at 2,000 volts pressure to the pumping station, a distance of about 4½ kilometres.

Water Storage of Power.—The Lynmouth electric supply station is driven by water from the Lynn, but the amount of available water does not always correspond with the load on the station. Consequently, a storage reservoir has been erected on an eminence, having a capacity sufficient to contain two or three days' supply of water. The reservoir, in fact, corresponds to the millpond in an ordinary water-mill plant.

Dynamo Nomenclature.—*Dynamo dimorphe* is the name by which *L'Industrie Electrique* is of opinion that a dynamo giving out continuous currents on one side and two-phase currents on the other should be known. The same journal announces that M. Hospitalier will to-day give an address to the Société Française de Physique, entitled "Générateurs et Transformateurs Polymorphiques d'Energie Électrique et leurs Applications Industrielles."

Royal Society.—The following 15 candidates have been selected by the Council of the Royal Society, to be recommended for election into the Society:—Mr. W. Bateson, Mr. G. A. Boulenger, Dr. J. R. Bradford, Mr. H. L. Callendar, Prof. W. W. Cheyne, Mr. R. E. Froude, Prof. M. J. M. Hill, Prof. J. V. Jones, Mr. A. E. H. Love, Mr. R. Lydekker, Mr. F. C. Penrose, Dr. D. H. Scott, Rev. F. J. Smith, Mr. J. W. Swan, and Mr. V. H Veley.

Technical Education.—The Master, Wardens, and Commonalty of the Society of Merchant Venturers of the City of Bristol have decided that their technical school shall henceforth be known as the Merchant Venturers' Technical College. In this connection the following nominations have been made: Principal and Professor of Chemistry, Mr. J. Wertheimer, B.Sc., B.A.; Professor of Mechanical Engineering, Mr. J. Munro, M.I.Mech.E.; Professor of Electrical Engineering and Applied Physics, Mr. W. Wilson, M.A.

Exports of Telegraph Wire and Apparatus.—The export trade of this country in telegraph wire and apparatus connected therewith, shows a little more activity than it did last year, although it is still a good way behind the trade of 1892. During the first four months of this year the value of the exports amounts to £452,018 as against £435,434 in the corresponding period of 1893, and £543,962 in the first four months of 1892. The exports last month amounted to £186,739, out of the £452,018, as against only £43,475 in April, 1893.

Telephony v. Traction.—It is reported that the Bell Telephone Company of Canada has brought an action against the Montreal Street Railway Company to recover damages for expenses incurred in placing return wires on its lines, the former use of the earth being rendered impossible by the interference caused by the electric railway circuits. The contention of the Telephone Company appears to be that it has obtained, by long usage, a vested right to the use of the earth for the purposes of its business, of which the action of the Railway Company has deprived it.

Fire Alarms.—Owing to the Post Office method of unearthing "earths" by pricking their wires, the single-wire telegraph fire-alarm circuits of the London County Council, which run in the same ducts as the Post Office wires, are frequently put in this way to earth, with the result that a false alarm ensues. One of the disadvantages of using telephonic fire alarms is, it has been pointed out, the necessity of using double-wire circuits. Under the conditions which obtain in London, however, this disadvantage would be converted into a positive advantage, since line-prickers would no longer make firemen's lives a misery with false alarms.

Electrolysis in Sugar Manufacture.—We are assured, says *La Lumière Electrique*, that sufficient success attended the electrolytic experiments made last season in connection with the manufacture of beetroot sugar to warrant their renewal this year. In addition to the experiments at French factories, some three-and-thirty German firms tried various electrolytic processes. The presence of one part of salt prevents the crystallisation of four parts of sugar, and the idea of certain electrolytic processes is to eliminate the saline constituents of the juices by electrolytic osmosis. In other processes no diaphragm is used, and the aim is to destroy the organic salts and generate alkaline carbonates.

Tinning Cast Iron.—A French company is said to have adopted a process of tinning cast iron by first covering it electrically with a coating of nickel and iron or cobalt and iron. One kilogram of sulphate, nitrate, or chlorate of nickel is mixed with 3 kilograms of the sulphate of iron and 1 kilogram of citric or tartaric acid; or 1·2 kilogram of sulphate, nitric, or chlorate of cobalt with 3 kilograms of sulphate of iron; this is dissolved in 100 litres of water, to which a sufficient quantity of a caustic alkali is added to neutralise the solution completely; a little bisulphate of potash, soda, or ammonia may be added to increase the conductivity. The cast iron is immersed, and a current is passed having a density of about 50 amperes per square metre of surface to be coated; about 7 volts are required.

Reduced Charges for Electricity.—The Kensington and Knightsbridge Electric Lighting Company announce that after July 1st next electricity supplied by them will be charged for at the rate of 6d. per unit, instead of 8d., as previously. A further economy the Company state can be effected by the use of higher efficiency lamps than those in general use at the present time. Such lamps (of various makes) can be purchased at the Company's Office. A certain number of lamps out of each case received by the Company are tested to ascertain that they are up to the required standard.——It is also announced that the Westminster Electric Supply Corporation have decided to reduce the price of electricity, after Midsummer, for motive power, cooking and heating to 4d. per unit where the supply is taken through a separate meter.

Train Electric Lighting.—It is reported that the London, Brighton and South Coast Railway Company has finally decided that their electrically-lighted trains are more serviceable than those lighted either by gas or oil. For some time, all three systems of train lighting have been tried upon this railway. The electrically-lighted trains not being required to be hauled to the charging station, as is the case with those illuminated with

Digitized by Google

gas, they are always ready for immediate use, and are estimated to render about 15 per cent. more service than the others. The first cost of gas, for a train of ten coaches, including the buildings and producer plant, is stated to be £700; that of oil, £120, while electrically-lit trains cost £400. The yearly cost of maintenance is, with gas £120 per train, with oil from £70 to £130, while with the electric light it is only £50 per train.

The Habit of Making Notes.—It is one of the merits of technical colleges, says *Engineering*, that they have taught engineers how to experiment and how to record. They have diffused the judicial frame of mind which takes note of every piece of evidence, whatever be its complexion. It is curious, however, that the men they turn out do not seem able to carry into business operations the same methods that they apply to matters of measurement. They will measure angles, deflections, and temperatures with the greatest minuteness, but very often they cannot explain how a job is getting on. Lately we heard an engineer declaim against the inability of his assistants to write intelligible reports concerning the matters under their charge. There is scarcely anything that recommends a young man engaged on outside work to his chief so much as explicit reports which show, not only how everything is getting on, but also what preparations are being made for difficulties or contingencies that may be expected to arise. It is not sufficient—at least not until a reputation has been made—for a man in this position to do all that is necessary to carry on his job; he must also keep the person on whom the ultimate responsibility falls informed of what has been done, and also of the plans he has formed for the future.

Wood Flywheels.—Commenting on the frequent occurrence of flywheel accidents in the United States, the *Engineer* observes:—"Flywheels of ordinary flywheel materials have struck such terror into the hearts of some American builders that they are making them of wood. One mill engineer writing to an American paper says:—'Why should men who would not dream of using cast iron in the tension member of a bridge use such an untrustworthy metal in the rim of a flywheel, where it is subject, not only to much higher tension, but more sudden changes of load? Since the bursting of the flywheel here, on October 15, 1891, we have abolished cast flywheels, and now have three wooden-rimmed ones, the first being 30ft. in diameter, with 110in. face, replacing the wrecked one, and the other two but slightly smaller. We have also built one 14ft. in diameter, with a 30in. face, and rim 12in. thick of plate steel, each plate being ½in. thick, 30in. broad, and extending half way around. This mass is riveted through and through, and I think it would be impossible to run it at a high enough speed to burst it. Its normal speed is 93 revolutions per minute, and it acts as a flywheel for a 1,500 H.P. tandem compound engine. All these wheels are giving entire satisfaction, and I for one want nothing more to do with cast-iron flywheels.' We wonder how they would get on with wood flywheels in a rolling mill where large cast wheels are often brought up in a revolution or two when running at over 100 per minute, and still remain able to do another round turn? Cast steel pulleys are now being used for high peripheral speeds, and have been found to be very safe.'

Opening of the Cambridge Engineering Laboratory.—This laboratory was formally opened, as announced, last Tuesday afternoon, by Lord Kelvin. Upwards of £5,000 has been subscribed, including £1,000 from the late Chancellor, the Duke of Devonshire, and, in addition, valuable presents of plant and appliances have been given. The University contributed £1,000. The Vice-Chancellor, in a brief speech, said that the occasion on which they were assembled was a novel one, the opening of a building to be devoted to the teaching of engineering. Some had doubted the wisdom of the University in attempting this new study. To Prof. Ewing's exertions and indefatigable zeal was the erection of the building due. Lord Kelvin, in the course of his address, justified the addition of the teaching of engineering as part of the University curriculum, and maintained that true education consisted in providing the most efficient means for the equipment of persons for the battle of life; and although the old system of scientific education possessed great merit, yet for a profession like engineering it required to be supplemented by a method of teaching such as the laboratory would supply. The establishment of an engineering school at Cambridge had already drawn to the University a number of earnest, hardworking students, who, but for it, would not have joined the University. Their presence could not but benefit the whole University, while the *status* of the profession would be raised by the introduction of men who had the advantage of University culture. Prof. Kennedy, who was introduced as the parent of engineering laboratories, also spoke as to the advantages to be derived from the movement. Sir Frederick Bramwell, who humorously described himself as one of the mechanicians of the baser sort, said he was an example of the sort of person who had not had the benefit of a University education. He did not think he could ever have passed an examination, for he could never remember anything that would have been required of him by an examiner at the right moment. He had some little fear whether the danger did not exist of the future supply of engineers exceeding the demand. Their numbers had enormously increased of late years, but he was very sorry to say that the demand for their services was decreasing.

Manganese Steel.—Mr. Hadfield, in a Paper read before the Iron and Steel Institute, gave some interesting information about this material. A bar cemented in the ordinary manner became strongly magnetic compared with its ordinary condition, but being kept several months, the coercive power was lost, showing it to have been only feeble. In order to see the effect of forging and water-quenching, the same sample, now magnetic, was re-heated, forged, and water-quenched in the usual manner. To the author's surprise the sample then became equally as non-magnetic as in its original state. In order to further test this fact, a bar of manganese steel 15in. long, ¾in. wide, and ½in. in thickness, of usual non-magnetic quality, was cemented. It became magnetic. Half the bar was heated, forged, and water-quenched, the other half left in the state as received from the cementation furnace; the former, that is, the forged and water-quenched portion, was non-magnetic, whilst the other, or cemented portion of the same bar, was considerably susceptible to magnetic influence: thus a curious combination of magnetic and non-magnetic qualities was obtained *on the same bar*. Naturally enough, it might be thought to cementation was owing the entire change of properties noticed; but from the behaviour of other specimens not cemented, but merely heated for a long, continuous period, and which also lost their non-magnetic qualities, the author feels sure that the change is rather a question of continuous heating (probably changing or decomposing the particular form of carbon or carbide) than an increase or decrease of carbon such as produced by cementation or annealing. The heat treatment must be continuous for a considerable time, and probably also must be accompanied by a very slow cooling, such as would naturally occur either in the case in question or in the cementation process. This is specially mentioned, because merely heating manganese steel once or more for a short time, even to very high temperatures, close upon the welding point, will *not*, so far as can be detected, change its non-magnetic character. It was then thought it would be interesting to see what would be the effect of decarbonising manganese steel. It was naturally expected that this would be a troublesome operation. The annealing of this manganese steel was certainly more difficult of accomplishment, but by treating a thin bar, 3¼in. wide by $\frac{3}{32}$in. in thickness, the object was attained, the carbon being reduced to as low as 0·06 per cent., or, in other words, a removal of 94 per cent. of the amount originally present was effected. The sample being thin was naturally much scaled. The latter was removed, and the bar was found to possess very considerable magnetic qualities or susceptibility. The same experiments were then carried out as with the cemented samples. A strip now magnetic was heated to various temperatures, then forged and water-quenched, but in no case did it again become non-magnetic, as with the cemented or annealed samples. It was now persistently magnetic, though according to the analysis apparently no change in the chemical composition had occurred except as regards carbon.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 38.*)

Furnaces and Boilers.

Furnace Combustion.—When burned in a boiler furnace, fuel requires much more than the theoretical weight of air to effect its complete combustion, even when the air is supplied under perfect conditions. The reason for this is, that if only the theoretical amount of oxygen is supplied in a stream to the fuel, a great deal of the oxygen will pass through the grate without coming into contact with the fuel, owing the dilution of the oxygen by the products of combustion. To remedy this, and to ensure the contact of a sufficient weight of oxygen against the fuel particles, excess of air is always supplied to the furnace. In a slow draught the excess of air must be greater than in a rapid draught, because in the former the products of combustion loiter about the fuel and insulate it from the oxygen more than they do in a rapid draught. The greater part of the air is supplied between the fire-bars; but it is usually the practice to supply a little air, either continuously or at intervals, over the grate. The over-grate air will be regulated by the liability to produce inflammable gases over the grate, and should be directly proportional to the rate at which such gases are produced. With perfectly steady stoking, however, even with fairly bituminous fuels, over-grate draught is not necessary, provided a large amount of air be passed through the grate. The actual amount of air necessary for the best results, with any given furnace burning any given kind of fuel, should be found by trial, *i.e.*, by adjustment of the dampers, or otherwise the force of the draught, as the case may be. In fact, this is the only satisfactory way to determine it within a close approximation, and theoretical calculations on this point are of little practical value. On an average, ordinary coal stoked by hand in the usual ways requires about 24lb. to 25lb. of air per pound of fuel, during the steady burning, and about 10 to 15 per cent. more on putting a thick charge on the fire. The volume of this weight of air at ordinary temperatures will be about 320 cubic feet. With careful mechanical stoking it is possible to effect economical combustion with from 16lb. to 18lb. of air per pound of coal of average quality. If too little air is supplied imperfect combustion results, the gases will not be properly heated, and both the economy and steaming performance of the boiler will suffer. On the other hand, if too much air is supplied the furnace gases will be cooled by the great amount of cold air, and precipitation of smoke and soot will occur, while much of the heat will be carried uselessly away by the extra chimney gases. Cold air is usually supplied to the fuel, but in some instances an economy of from 5 to 10 per cent. of fuel has been obtained by supply air at from 150° to 300°F.

Stoking.—Ideal stoking may be said to consist in keeping a perfectly regular and even thickness of fuel over the grate; in varying this thickness according to the steaming requirements of the boiler, so as always economically to keep a steady head of steam; and in so gradually supplying fuel to the area of combustion as that there shall be no sudden evolution of combustible gas when it reaches that area. Uniform thickness is desirable on account of the necessity for uniform passage of air through the grate. If air passes in one place in excess, and in another place insufficiently, imperfect combustion must result. Only by having an even fire can the air be led to stream uniformly through it.

Thickness of Fire.—Generally speaking, it is easier to maintain a uniform stream of air in a thick fire than in a thin fire, for the variations in thickness are of less importance in the former than in the latter. The actual thickness must evidently be determined by the draught and the weight of coal to be burned per hour. Very thick fires can only be burned where a great pressure of draught is available. For a given weight of coal, a thick fire means a small grate area; and this will lead to the amount of heating surface exposed to the radiation of heat from the fire being small. As will presently be seen, it is well to expose a considerable amount of surface to this radiation, so that very thick fires are only used where compact grates are necessary. The following may be taken as representing average practice, assuming the boilers to be at their normal steaming rate. With moderate chimney draught, unassisted by forced draught, a thickness of from 3in. to 6in., equal to about 4½lb. to 9lb. of coal per square foot per hour, may be allowed; with rapid chimney draught, or where a moderate assistance is given by forced draught, the practice is from 6in. to 12in. or 15in. thick, equal to about 9lb. to 20lb. or 22lb. of coal per square foot per hour; while, where very high forced draught is used, as in locomotive practice, a thickness of 3ft. to 3½ft. may be allowed, corresponding to from 100lb. to 150lb. of coal per square foot per hour. These figures, however, are modified very much where small coal or coke is used; in either of these cases a larger area of grate being allowed. The fires also will be thicker at reduced loads.

Hand-Firing.—The methods of stoking may be divided into two classes: hand-stoking or firing, and mechanical stoking. These again have their sub-divisions. There are three common methods of hand-firing—(1) the coking system, (2) the spreading or sprinkling system, and (3) the alternate system. In all three the fuel is supplied at intervals, and never continuously; and the fire-door must be opened for the purpose. As a consequence, the thickness of fire must vary, not only according to the steaming but also according to the decree of the being who handles the shovel. This decree is rarely dictated by the wisest judgment, and the boiler suffers in consequence. Another result attending hand firing is that whenever the fire door is opened a rush of cold air will enter by it and chill all the heating surfaces, causing strains through contraction, and diminishing the boiler output by depositing soot and cooling the surfaces. The irregularities consequent on infrequent and improper hand firing are the chief source of avoidable loss in boilers. On the coking system, the fuel is first thrown on to a dead plate, or portion of the grate in which there are no perforations for the admission of air. Here the volatile matter is distilled by the heat of the fire, sufficiently slowly to ensure its meeting with enough oxygen for its combustion. After coking on the dead plate the fuel is pushed on to the firebars, where the solid portion is directly supplied with air. This is undoubtedly the best method of hand firing with fuel which contains much volatile matter. On the spreading system, the fuel is shovelled straight on to the fire-bars, the attempt being made to distribute it evenly. The alternate system consists in alternately charging fuel on the right and on the left half of the grate. This is a modified form of coking system, for the side on which the last charge was thrown will have a thicker fire, and will receive less air through the bars than the other side, so that coking will take place on this side.

Mechanical Stokers.—On the broad general principle that wherever possible, in machinery, the human element should be eliminated, and should be replaced by automatic machinery, as well as in the light of actual experience, mechanical stoking is far superior to hand firing. In mechanical stokers the fuel is supplied to the grate continuously, not at intervals, and there is no need for a fire-door to be opened for the purpose. The rate of supply can be adjusted to suit the steaming rate, and can almost as economically be adapted to low steaming rates as to the normal rate; while, owing to the evenness of the fire and the constancy of the temperature of the heating surfaces, the combustion is more perfect and the evaporation of water more steady—as well as being actually greater—than where the fire is fed irregularly. Only a class of finely-divided fuel, such as slack or coke breeze, can be supplied by mechanical stoking; but as this fuel is cheaper per ton than round coal, and as quite as high an evaporation per pound of fuel can be obtained from it, this fact is not a disadvantage against mechanical stokers. There are two classes of such stokers: the coking stokers and the sprinklers. In the former the fuel is fed on to the front of the grate, and is gradually worked backwards to the bridge end, where the ash and cinders fall into the ash-pit. Motion is usually given

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

to the bars in order thus to produce a steady travel of the fuel. In the sprinklers the fuel is scattered over the whole grate; but this class of stoker, though adapted to the use of very dry fuels, has not been generally adopted for electric power station work.

Vicars' Mechanical Stoker.—The extensive use of the Vicars' mechanical coking stoker in electric power stations, as well as in other classes of works, and the remarkable results obtained through its use, make it worth while for electrical engineers to pay special attention to this apparatus and justifies its full description in this treatise. In the accompanying pair of illustrations, Fig. 13 gives an end elevation, and Fig. 14 a longitudinal section of the latest pattern of Vicars' stoker fitted to the front of a Cornish boiler, this form of boiler having been selected for simplicity of drawing. With a Lancashire or other double-furnace boiler there would be two such stokers fitted to each boiler. The illustrations are drawn to scale, for a 7ft. boiler shell. The action of the stoker is as follows. Small coal is stored in the hopper, H, which, together with the other parts, is supported on the cast-iron frame, S. The fuel drops through

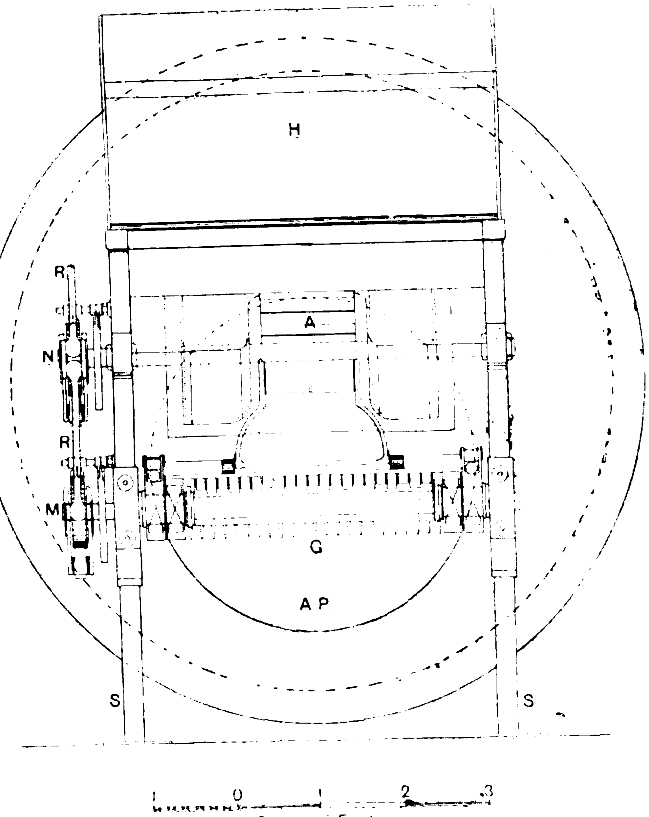

Fig. 13.

two openings in the bottom of this hopper, into two cylinders, one on each side of the fireplace. In each cylinder a piston is maintained in reciprocating motion, by means of the ratchet motion and cams at N. The out-stroke of the piston, or plunger, allows fuel to drop into the cylinder from the hopper; and the in-stroke of this piston forces the fuel from the open end of the cylinder on to the dead-plate, D P, where it is coked before dropping on to the fire-bars. The grate, G, consists of two sets of fire-bars, arranged alternately; and, by means of the ratchet and cam motion at M, the following motion is communicated to the bars:—Firstly, both sets are pushed inwards, carrying the fuel towards the bridge; then one set of bars is drawn back, while the other is stationary; and finally the second set of bars is drawn back, while the first set remains stationary. Then the whole cycle is repeated. At each in-stroke of the fire-bars, coal is carried forward; and by the out-stroke of each separate set the clinker tends to be broken up. If the fuel is highly bituminous there will be little or no loss of fuel through dropping into the ash-pit, A P, through the air spaces. The necessary motion is communicated to the mechanisms M and N, by the rod R, which receives a reciprocating motion up-and-down from an eccentric on a shaft; the shaft running the length of the battery of boilers, and actuating all the stokers. By varying the speed of this shaft, which requires only a trifling amount of power to drive it, the stoking rate of all the boilers can be varied simultaneously, or stopped altogether; and, by means of adjustments on the mechanisms, M and N, it is possible to separately adjust for each separate stoker the number of charges given to the fire, up to 240 per hour, and the amount of play of the fire-bars to-and-fro, up to 4in. Air is freely supplied to the fuel through the grate, as well as through a perforated air-plate over the grate at A; this plate being provided with a long slot for the introduction of a slicer without opening the fire-door. Fuel is usually supplied to the sets of hoppers by means of a trough running over the tops of the boiler fronts, in which trough there is a spiral conveyor, actuated by the same engine which propels the shaft for driving the stokers. The trough is supplied with charges of fuel from one point; and the most economical plan is to have the boiler-house so arranged that the fuel can be shot down from the stores to the conveyor,

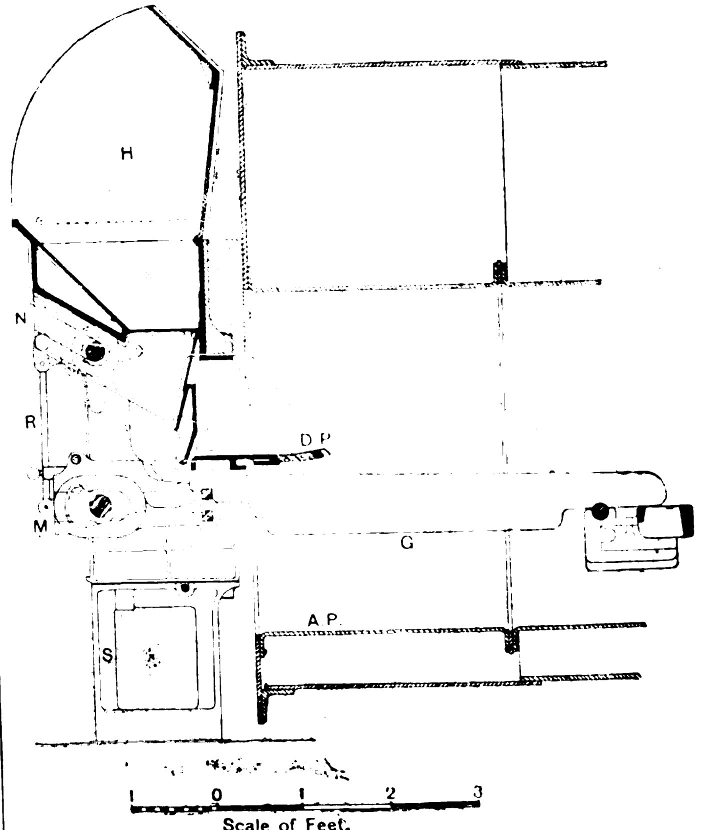

Fig. 14.

i.e., to have the boilers below the level of the stores. In several stations in which the author has made some inspection of these stokers, the fuel is raised to the conveyor automatically by means of buckets fixed to an endless chain, the elevator being worked by the auxiliary engine which drives the rest of the coal-handling plant.

This stoker will deal with highly bituminous slack without producing the least smoke, and will often with such fuel give a higher evaporative efficiency per pound of fuel than where good Welsh coal is stoked by hand. Clinker cannot form over the fire bars, owing to their perpetual reciprocating motion; so that a steady and uniform draught is maintained through the grate. Messrs. T. and T. Vicars have, through the courtesy of their representative, Mr. George S. Howatson, kindly supplied the author with particulars, given on the next page, of two sets of trials of their stoker, in the one as against hand firing with forced draught, in the other as against hand firing with induced draught.

At a large sewage pumping station, where the author has inspected a battery of 10 Lancashire boilers (8ft. by 30ft.) fitted with these stokers, not the slightest smoke can be seen

Digitized by Google

issuing from either of the two chimneys, although the weekly consumption of inferior bituminous slack amounts to about 250 tons; and the same may be said of every one of the factory chimneys where Vicars' mechanical stokers are used, which the author has from time to time had the privilege of inspecting. As examples of electric power stations, among these the Liverpool Overhead Railway generating station, and the electric supply stations at Manchester, Derby and Bristol, may be mentioned. In every case the author has found that an inferior and gassy quality of slack, sometimes even smudge, is in regular use, giving a higher boiler performance with considerably less cost of fuel than could possibly have been the case had the firing been done by hand. Since writing the above, the author has received a letter from Mr. Faraday Proctor, the Corporation Electrical Engineer at Bristol, in which he observes that the mechanical stokers have proved "most satisfactory, and even at fairly heavy loads smoke from the chimney is not visible." The fuel used is Welsh small nuts, but sufficient load has not been put on the station to test the smokelessness at full load. As a labour-saving device the mechanical stoker also calls for some notice. While it undoubtedly saves labour which would be necessary in manually handling and stoking the fuel, it introduces labour on account of the manipulation of the auxiliary engine, elevator, and conveyor, as well as in adjusting the feed of the stokers and the play of the bars, besides which some extra repairs—very trifling, however—will be necessary. In some stations it has been found that these items of labour-cost balance one another; in others, such as at the Liverpool Overhead Railway generating station, where there is a boiler plant of six Lancashire boilers, a net saving in labour has been effected by the use of mechanical stokers, amounting, at the station just named, to two men.

CONDENSATION IN STEAM-ENGINE CYLINDERS.

Two very interesting contributions to the literature of steam-engine theory have recently made their appearance, and help to elucidate a very recondite subject—the initial condensation of steam in the cylinder; and, by implication, to throw some light on the value of the steam jacket. Apparently this question, which has by no means been brought to a finality in either case, is one about which the highest authorities are at disagreement. Indeed, it seems as though no general solution of the question will be made; but that it will have to be dealt with separately, and on different lines for each separate class of engine. The first of these contributions is a selected Paper on "Experiments on the Condensation of Steam in Cylinders of Iron and other Metals," by Mr. Bryan Donkin, M.I.C.E., and is published in the *Proceedings* of Institute of Civil Engineers, Vol. CXV., p. 263. Probably no more competent authority on this subject, than Mr. Donkin, could be found; and electrical, as well as other engineers, will value this the latest extension of his well-known researches on the subject. We may remark in passing, however, that the conditions of Mr. Donkin's experiments much more nearly approximate to slow-moving pumping-engines than to high-speed electric light engines; the number of fillings and emptyings of his experimental cylinders being of the order of between 20 and 50 per minute. The cylinders used were of cast-iron, phosphor-bronze and glass; and arrangements were made whereby the ratio of cylinder capacity to the surface exposed to the steam might be varied. Experiments were made with both condensing and non-condensing working; and the special objects in view were the determination of (1) the variation of temperature throughout the thickness of the liner; (2) the weight of steam condensed per square foot of exposed surface; (3) the variation of the depth of heat-penetration into the cylinder walls at each steam filling, when the surface temperature was varied. It was found that when steam was admitted into an unjacketed glass cylinder, copious condensation occurred, in the form of large drops on the cylinder walls; while, when the cylinder was jacketed, the condensation was small and in the form of a fine mist or film. Instantly on release, the drops of water were seen to be in violent ebullition; and at the end of the exhaust the cylinder walls were dry, in the case of the jacketed cylinder, though there remained detached drops of water upon them where no jacket was used. It was further shown that within a certain distance from the inner surface of the cylinder, a pulsation of temperature synchronised with the fillings and emptyings of the cylinder; and that the depth of metal thus varyingly affected was greater in the unjacketed than in the jacketed cylinder.

Mr. Donkin observes that "It is now generally recognised by steam engine authorities that for the maximum economy in any engine the exhaust should be steam only, and not a mixture of steam and water; on the other hand, it should not be allowed to escape superheated, or again there will be a loss." If this principle is really established, the question of the value of the steam jacket is instantly settled in favour of the jacket. For it is impossible to have unjacketed expansion of saturated steam, even in a perfectly non-conducting cylinder, without liquefaction. But, after all, *is* this principle established? Are we indeed so sure that the steam jacket (or its equivalent, the superheater) is a necessary adjunct to the steam-engine? Looking at the case of high speed electric light engines, we find in the Willans engine an engine with neither a jacket nor a superheater, an engine which does not exhaust steam alone but a mixture of steam and water, and yet an engine which, supplied with a given pressure of steam and exhaust, will work as economically as any equally rated jacketed engine working between the same pressure and exhaust. Speaking of the Willans engine reminds us that the late Mr. P. Willans was by no means in favour of providing for a pure steam exhaust; and that he has naïvely observed that, in an ideal engine, steam would go in at one end and water would trickle out at the other. However, this is more a question of working liquefaction than of initial condensation; though it serves to show that water in the exhaust is not inherently objectionable. Incidentally, we may mention that an interesting Paper by Mr. Donkin, on "Heat Losses from Dry and Wet Cylinder Walls Exposed to a Vacuum, &c.," appears in the recently-issued *Proceedings* of Institute of Mechanical Engineers, No. 4, 1893.

The second Paper on this subject which we notice, read at the recent meeting of the Institute of Naval Architects by Mr. D. Croll, has suggested that the indeterminate element in cylinder condensation lies in the roughness of the cylinder-cover and piston surfaces, and points out that the heat absorbing area of surface might be considerably increased by a granulated, unfinished state of surface. The lesson to be learned, if this is so, is that all surfaces exposed to cylinder steam should be brought to a bright polish. Cylinder condensation, occurring as it does to an increased extent at reduced loads, is an important factor of ineconomy in electric power stations where the engine plant is not greatly sub-divided; and it is a matter calling for the attention of electrical engineers to seek to minimise it. As has been shown by Mr. Willans, the steam jacket is of little or no use for this purpose in the

Digitized by Google

class of engine which is best adapted to power station loads; but it might be worth while to try if machined and buffed cylinder covers and piston faces would help to save the steam by reducing initial condensation. It is worth remarking that the higher the speed of revolution for which an engine is designed, the less will be the condensation due to surface changes of temperature, while in rotary engines, such as the Parsons steam turbine, no condensation on this account can take place, though, unless the steam is superheated, liquefaction will arise from other causes.

NOTES ON THE WORKING OF THE BERLIN ELECTRICITY SUPPLY.*

The author began by remarking that the first part of his Paper contained an addendum to the Paper read last year by Dr. Kallmann, giving the results of the use on the Berlin Supply system of the apparatus therein described. The purpose of the two systems is to announce and localise any fault which may occur in the insulation of the mains in such a manner that the failure may be corrected before any serious disturbance of the supply takes place.

To briefly recall the principle of these arrangements will not be out of place. The first, that of Herr Agthe, is to use the pilot wires of the two outer mains of the three-wire network as signal wires for the automatic announcement of any disturbance; they are connected, namely, to the pole of the dynamo opposite to that which is connected to their conductor by a lead wire in the feeder junction box, and in the station pass round the coils of a relay. If by some damage done to the cable the pilot wire and main come into contact, the relay in the station rings violently, excited at 200 volts, and the fuse wire goes in the junction box; the relay announces which feeder the fault is on, and, therefore, in what district it has occurred.

The second system, invented by Dr. Kallmann, utilises the differences of potential set up in the ground by an earth on the mains. The pilot wires of the middle-wire are utilised, being earthed in as many places as possible, and connected through the feeder junction boxes through relays in the station again to earth. Every earth contact of the outer conductor means raising or lowering the potential of the earth in its vicinity, thus setting up a current in the pilot wire, and setting the corresponding relay in action, thus localising the fault.

All the stations of the Company, except the Markgrafenstrasse station, which only has the first of these systems, are fitted with both these alarm systems; and these during the last nine months have fourteen times signalled faults which have at once been removed. These alarms, chiefly given by the Agthe relays, included the following sources of leakage: three faults in house connections, six cases of water in the cable boxes, and five faults in the mains themselves. All cases where the leakage was only on the pilot wire are omitted.

The causes of these failures are interesting. Taking first the house connections, failures here are nearly always due to damp damaging the cables and junction boxes in damp cellars, especially in the Spandauerstrasse, where at times an alkaline moisture exudes from the walls which gradually soaks all wood and destroys its insulating properties; the current so set up destroys the wood completely. This source of failure, discovered by the alarm system, can be corrected by keeping the conductors and main switches off the walls. Penetration of water into junction boxes is a more serious affair. The electrolytic action set up not only decomposes the water but also the box itself, which is sometimes completely destroyed. In order to signal the presence of quite a small quantity of moisture the following plan was devised. In every junction box the wire connecting the pilot wire screws is bared in one place, and a piece of ebonite tube pushed over it; and as soon as the bottom of the box gets covered with moisture the relay, excited by 100 volts from the short circuit from pilot-wire to earth, rings until insulation is restored.

Of nine failures on the cables proper during the past year, five have been signalled by these apparatus. Of these nine only two were true failures of insulation, the others were generally due to accidental blows with a pick. Two of the unsignalled failures were on circuits having no pilot wires, and the other two were too small to set the signals in action. Thus the most frequent cause of damage is from outside, and not from failures of the cable itself. Although the signalling apparatus has meant increased expenditure, the money is well spent in keeping the cables in such good condition, and the author considers the apparatus indispensable.

* Abstract of a Paper read before the Elektrotechnischer Verein, by Dr. Passavant. See also *The Electrician*, Vol. XXXI., May 26, 1893, p. 103.

Leaving the question of alarm signals, the author takes up the question of power supply in Berlin. 358 electric motors, totalling 1,200 H.P., are now on the mains, 60 H.P. more are announced as ready to come on, and 50 H.P. more, at least, are in contemplation. In 1892-93 some 238,000 kilowatt-hours of energy were sold for power purposes, and in the first eight months of the current year, the total has reached 376,000. In the current year the total energy sold for motors will amount to about 10 per cent. of the whole supply. These motors are divided about as follows:—

———	Motors.	H.P.
Lifts	64	370
Ventilation and heating	103	130
Printing and paper manufacturing	78	287
Metal industries	24	106
Wood and leather works	6	30
Butchers	10	42
Washing, spinning, and weaving	35	94
Various	38	131

This large development of motor supply is due to the action of the Berliner Elektricitäts-Werke, which set out with the idea that a large power supply was desirable, and fixed their tariff at such a point as to encourage its development, the price being fixed in 1891 at 24pf., or 3d. per kilowatt-hour, about 40 per cent. of the price for lighting, and having been lately reduced to 2½d. The result of this policy has been to increase the summer all-day load from practically nothing to some 2,500 amperes. This load does not increase any of the working expenses, except the coal bill, and this is fully covered by the price charged. Curves given in the Paper show that, contrary to the universal experience with lighting, the number of hours a day run by each horse-power connected is increasing more or less steadily—from 1·25 in 1892 to somewhere near 1·8 now—thus showing that the motors are becoming less of a luxury or curiosity, and are used for factory supply in larger numbers. The author concludes with a few remarks on motor design, calling the attention of designers to the fact that consumers do not care to pay for power supplied to motors when running light.

PHYSICAL SOCIETY.

At a meeting of this Society on May 11, Walter Baily, M.A., Vice-President, in the chair, a mathematical communication on

"Electromagnetic Induction in Plane, Cylindrical, and Spherical Current Sheets, and its Representation by Moving Fields of Images,"

by G. H. Bryan, M.A. Part I., "General Equations," was read by Dr. C. V. Burton, who also explained some of the parts in greater detail. After mentioning that the magnetic field due to induced currents in thin conducting sheets placed near moving magnetic poles could be represented by moving trails of images of those poles, the author goes on to say that, in the Paper, the surface conditions which hold at the surface of the sheets are deduced directly from the fundamental laws of electromagnetic induction: 1. "The total current across any enclosed portion of a surface which always contains the same particles is equal to 1/4 π of the line integral of the magnetic force round the curve bounding the surface;" and 2. "The rate of decrease of the surface integral of magnetic induction across any enclosed surface space which always contains the same particles is equal to the line integral of electromotive force round the curve bounding the surface." By working with the scalar magnetic potential instead of rector potential the investigation is simplified. In addition to the above laws the author makes the usual assumptions that displacement currents in the dielectric as so small as to be negligible, and that the induced currents are distributed uniformly through the thickness of the sheet. On these suppositions the surface conditions satisfied by the potentials at the two sides of plane, sylindrical, or spherical sheets are determined, and, with an additional limitation as to the thickness of the sheet fulfilling certain conditions, extended to current sheets of other forms. In the latter part of the Paper a synthetic determination of the images in a plane sheet is given and expressed in the form of a definite integral.

In reading the Paper to the meeting, Dr. Burton pointed out several misprints in the proof.

Prof. MINCHIN showed that equation (1) of the Paper ($\Omega_2 - 4\,\Omega_1 = \pi\,\phi$ of constant, where Ω_2 and Ω_1 are the magnetic potentials at the two sides of the sheet, and ϕ the current function), would be deduced by purely mathematical reasoning, instead of being based on the laws of electromagnetic induction. Moreover, it was true for any functions whatever, and did not depend on ϕ being the current function. Equation (2) $\left(\frac{d\,\Omega_2}{d\,z} = \frac{d\,\Omega}{d\,a}\right)$

Digitized by Google

followed immediately from the fact that the magnetic force was continuous. The latter part of the Paper might be simplified by integrating the linear partial differential equation (15) $\left(\frac{d^2\Omega^1}{dz\,dt} - R\frac{d^2\Omega^1}{dz^2} = -\frac{d^2\Omega^1}{dz\,dt}\right)$ in the ordinary way, for the form was one for which the auxiliary equations are well known.

Dr. BURTON, in reply, said he thought Mr. Bryan's reason for developing the equation from the laws of electro-magnetic induction was to give his next work a physical rather than a mathematical basis.

A Paper

"On Dielectrics"

was read by Mr. ROLLO APPLEYARD. In testing the insulation resistance of celluloid by having a sheet pressed between the metal plates, the author noted that the resistance, which was very high, *decreased* as the time the testing battery was left on increased. The "electrification" (using the word to indicate the rate of diminution of galvanometer deflection) was therefore *negative*. The resistance also diminished greatly with increase of battery power, and a considerable amount of hysteresis was observed, the resistance at any given voltage, after a minute's electrification, depending on the previous history of the specimen. On making contact with the surfaces of the celluloid by mercury instead of by solid metal the abnormal results disappeared, little or no resistance—hysteresis or "electrification"—being present, and only a small diminution of resistance with increase of voltage. For a 6 mil. sheet the resistance between opposite faces 5½in. diameter was of the order 30 megohms, and one specimen broke down at 1,200 volts. The celluloid condensers used in the experiments were found to discharge slowly at first, and after a certain time the deflections of the galvanometer became reversed, and attained a steady negative value. This the author attributes to an E.M.F. of about 0·0006 volt between the mercury and celluloid.

Similar experiments on gutta-percha tissue showed no such E.M.F., and the "electrification" was normal. The resistance usually attained a maximum for voltages between 600 and 800. Although the tissue had a thickness of only 2 mils. (0·002"), it stood a pressure of 1,200 volts, and offered a resistance between circular faces of 5½in. in diameter of about 3,000 megohms.

The opaque white spots seen in celluloid under the microscope led the author to test the behaviour of mixtures of conducting and insulating materials. A strip of gutta-percha was warmed, and coarse brass filings scattered over it as thickly as possible. In spite of this the resistance was practically infinite, even when tested with 750 volts. A number of rods were made from mixtures of brass and gutta-percha in various proportions, and on testing these it was found that if the weight of filings exceeded about twice that of the gutta-percha, the resistance of a rod 20in. long ¾in. diameter was small (sometimes a fraction of an ohm), whereas a slightly smaller proportion yielded rods having resistances measured in thousands of megohms. Such rods were found to be affected by oscillating discharges in a manner similar to Prof. Minchin's "impulsion" cells and M. Branby's tubes of filings. Experiments were also made on the behaviour of such rods when subjected to high alternating pressures. This caused small local arcs to form along the rods, but did not permanently destroy their high resistance.

In connection with Mr. Appleyard's Paper, a

"Note on the Behaviour of Certain Bodies in Presence of Electromagnetic Oscillations."

by Prof. G. M. MINCHIN, M.A., was read by Mr. ELDER. Referring to the employment of impulsion cells, metallic films, &c., for detecting the nodes of electromagnetic vibrations, he says that so far the physical state of such bodies are too variable to be of service. Metallic services, formed by embedding fine metallic powders in films of gelatine, shellac, or sealing wax, are, as described in a previous communication to the Society, found to act as insulators, but become conducting when subjected to strong electromagnetic disturbances. After a current has once passed through such a film, its resistance is changed by very feeble impulses, whereas previously it failed to respond to strong ones. On breaking contact by removing the electrode from the surface, the film loses its conductivity, the time necessary to do this depending on the hardness of the matrix. The resistance of a film containing tin powder, measured between the rounded tips of two platinum wires 1cm. apart, varied under the electromagnetic impulses, from ∞ to 130 ohms. In conclusion the author points out that with films and tubes the whole phenomenon relates to change of resistance, whereas impulsion cells may have currents from external sources passing through them whilst in either the sensitive or insensitive states.

Mr. BRIGHT and Mr. ENRIGHT asked questions as to the electrification of gutta percha and the bridge connections in the resistance tests of the semi-conducting rods respectively, to which Mr. APPLEYARD replied.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

TO-DAY) FRIDAY, May 18th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 28, Victoria-street. The following Paper will be read:—"Notes on Gas-Engines," by P. W. Paget.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Splash of a Drop and allied Phenomena," by Prof. A. M. Worthington, F.R.S.

SATURDAY, May 19th.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture: "Colour Vision," by Capt. Abney, F.R.S.

TUESDAY, May 22nd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Modern Microscope; an Instrument for Recreation and Research," by the Rev. N. H. Dallinger, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Ballot for members. The following Papers will be read and discussed: (1) "Recent Types of Ferry Steamers," by Andrew Brown, M.Inst.C.E. (2) "The Birkenhead Ferry Boats, 'Wirral' and 'Mersey,'" by Charles Jones.

SOCIETY OF ARTS.

8 p.m. Applied Art Section. The following Paper will be read:—"Decorative Art in connection with Elementary Education," by Selwyn Image, M.A.

WEDNESDAY, May 23rd.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read:—"Liquid Fuels," by G. Stockpleth.

THURSDAY, May 24th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. Continuation of discussion on "The Cost of Electrical Energy," by R. E. Crompton, M.Inst.C.E.

FRIDAY, May 25th.

ROYAL INSTITUTION.

9 p.m. "Evening Discourse: The Development of the Astronomical Telescope," by Sir Howard Grubb, F.R.S.

Street Nomenclature.—A writer in a recent number of the *Chemical News* enumerates some of the streets, avenues, and public squares in Paris, named after eminent scientific men. In some instances the streets thus designated are appropriately placed near learned institutions with which the investigators' names were associated; in others, the names of men engaged in the same branch of science are grouped within small areas. It is pointed out that the "Jardin des Plantes is bounded by streets named respectively, Cuvier, Buffon, and Geoffroy St. Hilaire; while in the immediate vicinity are the streets Lacépède and the Place Jussieu. Elsewhere in Paris the following names occur:—Lamarck, Linnæus, de Saussure, and Humboldt. Near the École de Médecine runs the street Dupuytren, and in the same quarter the eminent physician Velpeau is honoured. Near the Hospital La Salpêtrière two English physicians lend their names to streets, Harvey and Jenner. In the neighbourhood of the Arc de Triomphe occur the names of the astronomers Copernicus, Galileo, Kepler, Euler, and Newton; elsewhere we find the streets Huyghens, Laplace, and Herschell. Mathematicians and physicists have not been forgotten, as shown by the occurrence of the following street names:—Biot, Pascal, Lalande, Lahire, D'Alembert, Dulong, Arago, Monge, Legendre, Ampère, Fresnel, Becquerel, Galvani, Volta, Franklin, and Faraday. Ampère, Galvani, and Faraday are near each other. Philosophy is represented by Descartes, Auguste Comte, and Bacon; engineering by Vauban, Watt, Stephenson, and Fulton; useful inventions by Bernard Palissy and Guttenberg; exploration by Christopher Columbus and Magellan. Chemists have received, however, a larger share of the honours than any other single class, not even excepting men of letters. Thus we find streets named after the French chemists Bayen, Berthollet, Cadit, Chaptal, Darcet, Daguerre, Gay-Lussac, Lavoisier, Langier, Orfila, Parmentier, Payen, Raspail, Réaumur, Rouelle, Thénard, and Vauquelin; the Swede, Berzelius; and the Englishmen, Davy, Faraday, Priestley, Cavendish, and Watt."

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.

Editorial, Publishing, and Printing Offices:

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams*: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

'THE ELECTRICIAN' *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months. s. d.	6 months. s. d.	12 months. s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of*—

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d. post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free. Also in German, 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

In Preparation. Very fully illustrated.

ELECTRIC LAMPS AND ELECTRIC LIGHTING.

Being Four Lectures delivered in April-May, 1894, before the Royal Institution, by Prof. J. A. FLEMING, M.A., D.Sc., F.R.S.

NOW READY.

Volume XXXII. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad, carriage extra.

Cases for binding Volume XXXII., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

PRIORITY.

SOME little time ago a New York contemporary published a series of articles from the pen of Miss MARY A. HENRY—extracts from which appeared in these columns at the time—setting forth the bases of her father's claim to be called the first and true discoverer of "magneto-electricity." In attaching such paramount importance to mere priority, Miss HENRY did no more than give her adhesion to the widely-accepted and influentially-supported doctrine that questions of the kind should be settled solely by the date of publication, without, as HELMHOLTZ says, "considering the ripeness of the research."

Encouraged, probably, by the success of her former literary effort, Miss HENRY has more recently undertaken the task of assigning to JOSEPH HENRY his proper place in the history of the electro-magnetic telegraph. The place allotted is, it is, perhaps, needless to say, the first. A perusal of this second series of articles, now appearing in the *Electrical Engineer* of New York, would, no doubt, show that this second claim has been made good. But the discovery of the "intensity" electro-magnet is in a very different category to that of the phenomena connected with the interactions of electric and magnetic circuits. The "intensity" electro-magnet is the very soul of the electric telegraph, and was recognised as such from the commencement. Had the Princeton Professor been possessed of the modern mania for patenting the results of his laboratory investigations, the files of the United States Patent Office would have been enriched by at least one intrinsically valuable invention, and the patentee possibly by an untold tale of dollars. The importance of priority the moment a philosopher descends to inventing is obvious; it is the all-in-all, the alpha and omega of the trade, and cannot be over-estimated. The inventor's attachment to priority has, in short, a purely business basis, and need not, therefore, be objected to as irrational. The pocket argument, however, does not apply to the discoveries of pure science. The hot haste of the patentee we can under-

Digitized by Google

stand, not so the pot-hunting of the physicist. Whence comes this feverish eagerness to be first, which is so characteristic of latter-day research, always to its detriment, and often to the delight of the Philistine, ever glad to see the philosopher come down from his pedestal and display to the world at large a few of the failings of common men? Does it come from that "rage for fame" which "attends both great and small," and makes men think it "better to be damned than mentioned not at all"?

Now the articles which dealt with the conflicting claims of MICHAEL FARADAY and JOSEPH HENRY, albeit in excellent taste, the author refusing to allow her close relationship to one of the candidates to intervene at the expense of her fairness and courtesy, left the impression that the true significance of each of the many factors that go to make up the ultimate value of a scientific discovery had been somewhat misapprehended; a failing, indeed, common to most literature of the kind. Stress was rightly laid upon the widely different conditions under which FARADAY and HENRY worked: the one in a well-equipped laboratory, with ample leisure, and amidst books and stimulating society; the other only able to devote a few weeks every summer to research, and living out of the world in a small town 150 miles from New York. But the real objective of Miss HENRY's incursion into the fields of technical literature, the idea with which proof was piled on the top of proof *ad demonstrandum* and *ad nauseam*, was to secure a verdict for JOSEPH HENRY—to make it known unto all whom it might concern that the dark horse away out in the American backwoods had passed the winning post at least half a head in front of MICHAEL FARADAY. In the investigator himself a wish to be first may perhaps be excused by reason of the inherent defects of the human mechanism, but in settling the precise position of a niche in the Temple of Scientific Fame, the undue weight that is attached to mere matters of date is wholly without excuse. It has no foundation in reason, and should have none in sentiment. The assiduity of the scientist-historiographer tends greatly to foster this belief in the supreme importance of being first. A day amongst the dry-as-dust files of the Patent Office, a visit to the British Museum library, the possession of a moderately-sized collection of old volumes, and you have all the ingredients necessary for the unearthing of the real genuine No. 1, who somewhere in the dark ages of Science was the only son of a widowed mother, learnt three languages by sitting up late at night, and imbibed science in lieu of beer during the dinner hour. If this exhumed No. 1 be finally admitted within the pale of science, after due discussion and examination of his claims, the names of the discoverer of the discoverer and of the discoverer of the discovery will in all probability have become so linked together that, like twin stars, they will for ever revolve around each other in the scientific firmament, and be reckoned of equal magnitude.

About two things, and two things only, should history concern itself in dealing with the personal equation of a scientific discovery, and these things are its intrinsic value and the manner in which it was made. As it is, intrinsic worth counts, indeed, for something; but opportuneness, date, and mode of publication, and practical possibilities count for much more. That one man had a clearer idea of what he was aiming at, or a more intelligent perception of the true meaning and bearing of what he had found, will avail him but little in face of the fact that someone else stumbled upon the same object, it may be, quite four-and-twenty hours before. It is the knowledge of this that leads so many to sacrifice thoroughness and lucid exposition in their desire to "take date." Hence comes the modern custom of publishing, step by step, the blind gropings of the laboratory:—"Certain experiments which I have been making on the electrolysis of aniline have casually led me to suspect that there is a fundamental flaw in the Newtonian theory of gravitation; more anon (April 1st). Further experiments have convinced me of the absolute correctness of my conclusion; I have now only to test the accuracy of my electrostatic voltmeters, &c. . . . Regret to say that a redetermination of H and g in my laboratory has revealed grave inaccuracies, vitiating conclusion jumped to on April 1st, so can only take date for my 'suspicion.'"

Notwithstanding this rage for taking date, two and two, we doubt not, will continue to the end of time to make four, and the truth to be that the honour awarded to a discoverer ought in no way to be lessened, because, totally unknown to him, someone else has carried out an investigation on parallel lines, and has anticipated his conclusions. The intellectual triumph is the same in either case, and the waste of thought and experimental skill are due to the defects of the system. It does not follow that a man is entitled to "all the honours of war" who shuts himself up, and deliberately ignoring the work of his scientific ancestors and contemporaries, magnanimously gives to the world results long since common property. An indispensable preliminary to the solution of every scientific problem ought to be to make oneself acquainted with the results of previous work in the same field, but in these days of verbiage and voluminousness an investigator who would exhaust the literature of his subject before commencing his own attack runs a risk of never beginning—of not seeing the forest for the trees. After all, to quote from HELMHOLTZ once more, "All this literature of untried and unconfirmed hypotheses has no value in the progress of science. On the contrary, the few sound ideas which it may contain are concealed by the rubbish of the rest; and one who wants to publish something really new—facts—sees himself open to the danger of countless claims of priority unless he is prepared to waste time and power in reading beforehand a quantity of absolutely useless books, and to destroy his readers' patience by a multitude of useless quotations." In the past a lack of proper means of intercommunication led to much wasteful working on parallel lines. To-day the danger is that this absurd ambition to publish first "without considering the ripeness of the research," in order to secure the equivocal advantage of priority, leading as it does to the publication of an immense amount of "untried and unconfirmed hypotheses," will equally result in wasteful working on parallel lines. The volume of the stream of scientific literature must of necessity continue to grow so long as men continue to burrow into nature. Let us, however, dry up one perennial source of printed inanities by setting a right estimate on the minor question of date.

REVIEWS.

Water or Hydraulic Motors. By PHILIP R. BJÖRLING. (London: E. and F. N. Spon. New York: Spon and Chamberlain. 1894.)

The author of this little book tells us, in his preface, that he has been induced to write it because "all the books previously published are too abstruse in mathematics, and not practical;" and he assures us that "deep, and in many cases useless, calculations are avoided." We, therefore, passed on to read the book, with the anticipation of something very practical; and we may perhaps have expected to find some royal road which is a short cut to the intricacies of mathematical treatment. We cannot say that either of these expecta-

Digitized by Google

tions were realised, and especially in regard to the latter, we have been but confirmed in our conviction that there is no satisfactory short cut or royal road to the study of hydraulic or any other branch of mathematical engineering. In his haste to cut away all appearance of mathematical equation and form from his pages, the author has inflicted upon his readers such rigmaroles as the following:—"The loss of energy then equals the weight of the water multiplied by the square of the higher velocity in feet per second, divided by 64·4, and the result multiplied by the number of times the column is arrested per minute, minus the weight of the water multiplied by the square of the lower velocity in feet per minute, divided by 64·4, and the result multiplied by the number of times the column is arrested per minute." Almost breathlessly we exclaim, How much better and more neat this would have been if in the shape of a little formula! Can any "higher mathematician" solve it in its present form? Again, in his extreme desire to make the principles of hydraulics appear simple and non-mathematical, the author makes them simpler than they really are, and thus misleads where he professes to instruct. Thus, in an early chapter on "Hydraulics Relating to Water Motors" we find the statement that "the wetted surface in the motor should be small, as friction is proportional to that surface," a statement which, when taken by itself, and without qualification in regard to the velocity and section of the flow, is a completely erroneous principle of design. This chapter, which professes to introduce the reader to the elementary principles, is nothing more than a badly arranged collection of mere assertions, without the slightest attempt at proof; and many of these assertions are either completely wrong or are limitations of the truth. A serious defect in the chapter, and indeed in all the theoretical chapters, is the absence of any definitions of the hydraulic terms used. A curious feature of the chapter is the "table of square and cube roots, advancing by *half-inches*;" as also is the absence of any table of 5th powers.

The author is more correct and more happy in the later chapters, in which, for the most part, he confines himself to a series of descriptions of water-wheels, turbines, and water-pressure engines. His descriptions, too, are well illustrated with numerous drawings, which have the merit of being something more than mere pictures. The illustrative part of the work is, indeed, one of its best features, and considerably compensates for defects in other respects. The author has, perhaps, been too careful to perpetuate older types of machinery, and not careful enough to give due proportion to the later and more efficient types; but that, in an elementary and unscientific work which this claims to be, is perhaps a pardonable defect. Water-wheels and turbines are treated of in about 110 pages, the remaining 144 pages being concerned with hydraulic rams and water-pressure machinery. The separate chapter on "Circumferential-flow Turbines" is based on a questionable classification; and of the types selected for illustrating this class two are inward-flow turbines and the other is an outward-flow turbine. The sole ground upon which we can recommend this work is that it contains a number of illustrated descriptions of water motors, old and new; but the work is untrustworthy as a treatise on the principles either of the construction or of the action of these engines.

Electroplating. By J. W. Urquhart. Third Edition. (London: Crosby Lockwood and Son. 1894.)

While the preface disclaims for this book any concern with electro-metallurgy, it professes that it has been brought fully up to date. No reference whatever is made to Mr. J. W. Swan's method of obtaining high-current density in copper plating or to the silver-cadmium alloy. Eleven pages at the end of the book relate to the use of dynamos, and contain very insufficient information about current density and voltage. The book should be entirely rewritten on modern lines.

Electric Light Installations. By Sir David Salomons. Vol. II. Seventh Edition. (London: Whittaker and Co. 1894.)

This volume consists of descriptions, with many illustrations, of various kinds of machinery and apparatus, including several obsolete and nearly obsolete examples. It is not confined, as was the author's original work, to private house work, but touches on supply stations, mining, &c., but in a very superficial manner. The subject is treated neither from the amateur, the professional, the critical, or the scientific point of view. It is promised that Vol. III. will more particularly deal with the method of working, so that the detailed information which some might naturally look for in this book, will be found in the one that follows. It is, therefore, impossible to regard the present volume as other than a set of illustrations of a forthcoming work.

THE RELATION OF MATHEMATICS TO ENGINEERING.*

BY JOHN HOPKINSON, F.R.S.

(*Concluded from page 43.*)

Submarine telegraphy yields some interesting examples of the application of the higher mathematics. When a cable across the Atlantic was first seriously entertained, the first point to be settled was, how many words a minute could be sent through such a cable. This was the most practical question possible. Upon the answer depended the prospect of the cable paying commercially if successfully laid. The matter was dealt with by Prof. Thomson,† of Glasgow, now Lord Kelvin. He showed that the propagation of an electric disturbance in a cable could be expressed by a partial differential equation, and that the solution of this equation under certain conditions applicable to practice could be expressed either by a definite integral or by an infinite series. The values of these were calculated, and hence before an Atlantic cable was laid at all it was known how long it would take a signal to reach the opposite shore, and how much its intensity would be diminished in transmission. Referring to Fig. 5, abscissæ represent time, reckoned from the time of making contact at the sending end of the cable, ordinates the currents at the receiving ends, curve (1) gives these currents when the contact at the receiving end, after being made, is continuously maintained. It will be observed that for a time a there is hardly any current at the receiving end, that then the current rapidly increases, and attains to half its final value after a time equal to about $5a$. Curves (1) . . . (7) show the currents at the receiving ends when the contact is made at the sending end maintained for times a, $2a$ . . . . $7a$ respectively, and then broken. Looking at curve (1) one sees how small is the amount of current and how long it lasts compared with the time during which contact is made. The time a depends on the length and character of the cable; it is equal to $kcl^2 \log_\varepsilon \frac{4}{3} / \pi^2$, where k is the resistance per unit length, c the capacity per unit length, and l the length of the cable. The knowledge of what is the commercial value of a cable depends on a knowledge of the value of a, and this cannot be obtained without knowing the differential equation $ck\frac{dv}{dt} = \frac{d^2v}{dx^2}$,‡ to which I have referred, and its by no means simple solution either as a definite integral or as an infinite series. So far as I know, this piece of higher mathematics cannot be evaded by any mere elementary treatment. The transmission of disturbance in a cable is quite different from the transmission of sound waves in air, which move with constant velocity. If the cable be doubled in length, it takes four times as long for the signal to pass through it instead of just twice as long, as would be the case if it were a proper wave motion. In fact the time of passage between the making of contact at the sending end of the cable and the beginning of the resulting disturbance at the receiving end, varies as the square of the length of the cable. The mathematical theory is exactly the same as that of the transmission of heat in a plate, one surface of which is suddenly exposed to a temperature different to the temperature of the plate. This is constantly occurring in the application of mathematics—one piece of mathematical work serves for many physical problems having apparently little in common. Fourier long ago discussed the heat problem, little dreaming that his analysis would be just what was wanted for ascertaining how fast signals could be sent across the Atlantic by a system of telegraphy which in his days had not even been projected in its simplest form. The same differential equation also gives the theory of the transmission of telephonic messages through cables; but the solution is then easier, and tells us exactly why it is so much more difficult to speak through 100 miles of cable than through 1,000 miles of overhead line.

* The "James Forrest" Lecture, delivered before the Institution of Civil Engineers, May 3rd.

† "Mathematical and Physical Papers," Vol. II., p. 61. Sir W. Thomson.

‡ v is the potential, t the time, and x the distance from the sending end of the cable.

Digitized by Google

As I have just stated, the differential equation of the disturbance in the cable is $c k \frac{d v}{d t} = \frac{d^2 v}{d x^2}$. A musical note of period T spoken into the cable through a telephone is properly represented by $A \sin \frac{2 \pi t}{T}$; the disturbance in the cable will be—

$$v = A e^{-x \sqrt{k c \pi / T}} \sin \left(\frac{2 \pi t}{T} - x \sqrt{k c \pi / T} \right),$$

as may be easily verified by differentiating. This equation tells us everything. It tells us the rate at which the waves diminish with the distance. This rate increases with the resistance, with the capacity and with the frequency. If the capacity is at all considerable the diminution is rapid. The velocity of the waves is not the same for all frequencies, as is the case with waves in air, but varies as the square root of the period, so that if two notes were sounded the high note would arrive after the low notes, and the resultant effect would be entirely destroyed. Here, again, it is difficult to see how the differential equation and its solution can be evaded.

Though the history of the telegraph dates only from a little more than 50 years ago, it is ancient in comparison with the other great applications of electrical science, which have received their development during the last 15 years. Here again mathematics which are not quite elementary have played their part. In the theory of transformers we find another illustration of the need of knowing how formulæ are obtained if they are to be correctly applied. The early transformers were made with unclosed magnetic circuits; there was an iron core, but the lines of magnetic force passed through air for a considerable part of their path. In this case a complete mathematical theory was not very difficult. But speedily closed magnetic circuits were found to be

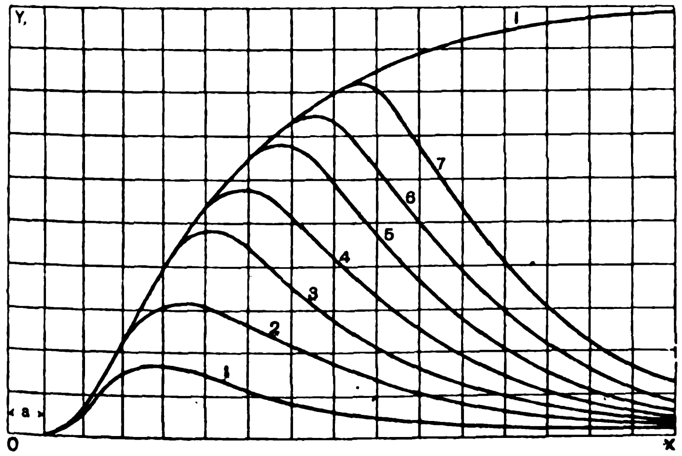

Fig. 5.

better, and the relation of magnetic induction and magnetic force became all important. If anyone were to apply mathematical formulæ, which were true for the earlier transformers, to the later ones, his results would be inaccurate. Indeed a wholly different method of attack on the problem was needed, taking account of the facts as they are, and applying results which were true of older apparatus to cases essentially distinct.*

The employment of alternating currents has brought into use, as a necessity for understanding the actually observed phenomena, a great deal of mathematics. Why is the apparent resistance of a conductor greater for an alternating current than for a direct current? And by resistance I do not mean the quasi-resistance due to self-induction.† The mathematical electrical theory is ready with an answer; it is ready, too, to tell us how the difference depends upon the frequency of the current and on the size of the conductor. In the case of a cylindrical conductor the solution involves a knowledge of Bessel's functions. We learn that if the current has a high frequency, or if the conductor be large, there will be very little current in the centre of the cylinder, and that therefore for any practical purpose the centre of the cylinder might just as well not be there; the current is largely confined to the part of the conductor near to its surface. The currents at different depths in the conductor attain to their maximum values at different times; those near the surface of the cylinder occur before those at some distance from the surface. The mathematical conditions are expressed by the same equation as is used to express the disposition of heat in a cylinder the surface of which is submitted to a periodic variation of temperature. Anyone who had thoroughly mastered the heat problem would be quite prepared to deal with the problem of currents in a conductor. It cannot be too often repeated, any piece of pure mathematics which finds one application to a physical problem is almost sure to find, in exactly the same form, applications to other problems which superficially are absolutely distinct. The differential equation in this case is $k c \frac{d v}{d t} = \left(\frac{d^2 v}{d r^2} + \frac{1}{r} \frac{d v}{d r} \right)$, the similarity of physical condition to the problem of linear propagation of heat is close, but the mathematics differs materially owing to the presence of the term $\frac{1}{r} \frac{d v}{d r}$ in the equation. Mathematics deals with the relation of quantities to each other without troubling as to what the physical meaning of the quantities may be. Hence it is that the mathematical treatment of two such problems as the distribution of currents in a cylindrical conductor and of heat in a cylinder is identical, whereas the treatment of the distribution of heat in a cylinder is quite distinct from the treatment of the distribution of heat in a sphere or in a solid bounded by two parallel planes.

A curious phenomenon was observed in the large alternate-current machines at Deptford when connected to the long cables intended to take the current to London. The pressure at the machines when connected to the conductors was, under certain conditions, actually greater than when not so connected. The phenomenon is one of resonance very analogous to the heavy rolling of ships when the natural period of roll is about the same as the period of the waves.* The period of the alternating-current corresponds to the period of the waves, the self-induction of the machine to the moment of inertia of the ship, the reciprocal of the capacity to the stiffness of the ship, and the electrical resistance of the conductors to the frictional resistance to rolling. The mathematics in the two cases is then the same. The effect was predicted long before it was observed in a form calculated to cause trouble.

A problem which is still agitating electrical engineers is that of running more than one alternate-circuit dynamo machine connected to the same system of mains. Before the matter became one of practical concern, it was considered in this room, and it was shown mathematically that it was possible to run independently-driven alternators in parallel but impossible to run them in series. That is to say, that if two alternators were connected to the same mains they would tend to adjust themselves in relation to each other so that their currents could be added, but that if an attempt were made to couple them, so that their pressures should be added, they would adjust themselves so that their effects would be opposed.†

Perhaps of all engineering problems which have received their solution in the last hundred years, that of the greatest practical importance is the conversion of the energy of heat into the energy of visible mechanical motion. The science of thermodynamics has advanced along with the practical improvement of the steam engine. By its aid, particularly by the aid of the so-called second law, we know what is possible of attainment by the engineer under given conditions of temperature. I must not trench on the subject of one of my successors, but I may point out that our knowledge of the second law of thermodynamics was first developed by means of mathematics, and that to-day its neatest expression is by means of partial differential coefficients. The two most notable names in connection with the development of the second law of thermodynamics in harmony with the first are those of Kelvin and Clausius; both dealt with the subject in a mathematical form not comprehensible to those who have not had substantial mathematical training.

Illustrations such as these might be multiplied almost indefinitely. They show that the advancement of the Science of Engineering has been aided in no inconsiderable measure by the labours of mathematicians directly applying the higher mathematical methods to engineering problems. They show, too, one way in which respect for a formula may be dangerous, one way in which it is true that mathematics may be a bad master. In St. Venant's problems we have an example in which the use of older results of limited application in cases where the assumptions on which they rest are not true will mislead. The examples show the proper remedy; it is a more complete application of mathematical methods. The error is just one which a man will make who has the power to use a formula without a ready understanding of how it is arrived at. A practical man, ignoring mathematical results, might or might not escape the error of supposing that a triangular shaft would break at the angles under torsion; the half-educated mathematician would certainly fall into the snare from which complete mathematical knowledge would deliver him. You can only secure the services of that good servant, mathematics, and escape the services of a bad master by thoroughly mastering the branches of mathematics you use. The mistake caused by the wrong application of mathematical formulæ is only to be cured by a more abundant supply of more powerful mathematics.

There is another drawback to the use of results, taken, it may be, out of an engineering pocket-book by those who are not prepared to understand how they are reached and on what foundations they rest. The educational advantage is lost. The close observation which enabled the earlier engineers to proportion their means to the ends to be attained was no doubt very laborious, and the results could not be applied to cases much different from those which had been previously seen, but the effect on the character of the engineer was great. In like manner, to thoroughly understand the theory of an engineering problem makes a man able to understand other problems, and in addition to this precisely the same mathematical reasoning applies to many cases. The mere unintelligent use of a formula loses all this ; it leaves the mind of the user unimproved, and it gives no help in dealing with questions similar in form though different in substance.

But even the use of mathematics by competent mathematicians is not without drawbacks. Mathematical treatment of any problem is always analytical—analytical, I mean, in this sense that attention is concentrated on certain facts, and other facts are neglected for the moment. For example, in dealing with the thermo-dynamics of a steam engine, one dismisses from consideration very vital points essential to the successful working of the engine, questions of strength of parts, lubrication, convenience for repairs. But if an engineer is to succeed he must not fail to consider every element necessary to success ; he must have a practical instinct which will tell him whether the instrument as a whole will succeed. His mind must not be only analytical, or he will be in danger of solving bits of the problems which his work presents, and of falling into fatal mistakes on points which he has omitted to consider, and which the plainest, intelligent practical man would avoid almost without knowing it.

Again, the powers of the strongest mathematician being limited, there is a constant temptation to fit the facts to suit the mathematics, and to assume that the conclusions will have greater accuracy than the premises from which they are deduced. This is a trouble one meets with in other applications of mathematics to experimental science. In order to make the subject amenable to treatment, one finds, for example, in the science of magnetism, that it is boldly assumed that the magnetisation of magnetisable material is proportional to the magnetising force, and the ratio has a name given to it and conclusions are drawn from the assumption, but the fact is, no such proportionality exists, and all conclusions resulting from the assumption are so far invalid. Wherever possible, mathematical deductions should be frequently verified by reference to observation or experiment, for the very simple reason that they are only deductions, and the premises from which the deductions are made may be inaccurate or may be incomplete. We must always remember that we cannot get more out of the mathematical mill than we put into it, though we may get it in a form infinitely more useful for our purpose.

Engineers no doubt regard their profession from very different points of view ; some think it a mere means of making money ; some regard it as an instrumentality for benefiting the race, whilst others again delight in it as an interest in itself, and delight in it most of all when new knowledge is added to that which we know already. It is just the same with the medical profession ; some attend patients for the guineas they receive, some give a very high place to motives of benevolence, whilst others love it as a field where new knowledge may be found and the delight of discovery enjoyed. In regard to the first class of engineers, I have no doubt a little skill in managing a board of directors or impressing a committee of Parliament will be much more useful than a great deal of mathematics. Let him manage his board and buy his mathematician, and it is very probable he will make much more money than the mathematician or any other person of skill whom he may employ. But we cannot all of us make money in this way. In the future it is likely that educated men will have to work harder and receive less, and it is a great thing if their work can be made itself a joy, and surely this can best be by a thorough understanding of the reason of all they do by the feeling that they have full competence to form their own judgments without depending much on the authority of others. This can only be, in the words of Sir John Herschel, by a "sound and sufficient knowledge of mathematics, the great instrument of all exact inquiry, without which no man can ever make such advances in any of the higher departments of science as can entitle him to form an independent opinion on any subject of discussion within their range."

After all, in any department of applied or pure science, the highest satisfaction comes from accomplishing that which no one has done before, from disclosing what no one hitherto has known. If a department of the arts or sciences ceases to advance and becomes simply the application in known ways of known principles to obtain known ends, that department has lost its charm till the time comes for a fresh advent of change and development. To effect such advances it is easy to show that mathematics is a most necessary instrument. Here it is no drawback that the mind of the discoverer is too analytical ; he may deal at his pleasure with one aspect of a problem, and it does not detract in any way from the value of his solution that he does not touch on incidental matters. Some of you who love the interest of continual advance in our science and practice, may look forward with a shade of sadness to a possible time when all is done or known which can be done or known, and the work of the engineer shall be merely applying principles discovered by his predecessors. In such a state, when the experience of the older generations shall control the practice of to-day, the free use of mathematical methods may be effectually superseded by the application according to rule of mathematical formulæ. But it would be a much less interesting condition than the constant change of to-day, when the practical experience of ten years ago is in many departments rendered worthless by later discoveries. But we need not fear that such a time of petrifaction will come so long as, whilst reverencing the discoverers who have added to our knowledge, we endeavour to replace their methods by better, and expect that those who come after us will, in their time, improve upon ours. Our knowledge must always be limited, but the knowable is limitless. The greater the sphere of our knowledge the greater the surface of contact with our infinite ignorance.

TESTING FOR GROUNDS ON INCANDESCENT CIRCUITS.*

BY AUSTIN S. B. LATCH.

After reading Mr. G. L. Thayer's article on "Grounds on Incandescent Circuits," in the *Engineer*, of April 11th, I send you a method I have used for about five years, and think it will commend itself to your readers, as no lights are disconnected in locating the ground. With slight modifications, the system can be adapted to alternating, as well as direct current, and either isolated or central stations. I devised the method from some experiments made by Mr. M. M. Waddell, of the Waddell-Entz Company, and myself, at the Edison station, in Detroit, in our attempt to locate grounds on the underground system by other than the "cut and try" method.

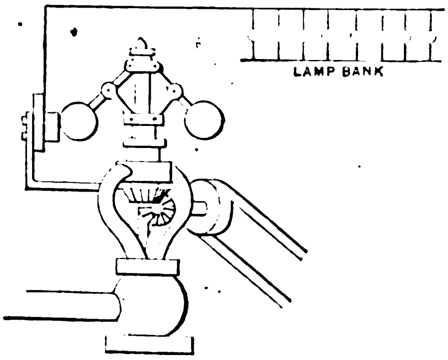

FIG. 1.

The mechanical stokers in that station are run by a small engine, with the ordinary ball governor. We used this governor to interrupt the current from a bank of lamps, as shown in Fig. 1. An iron arm is fastened to the governor frame ; this carries a block of wood, on which is a metal strip. The governor balls strike this strip and thus complete the circuit to ground through the engine. This gave an interrupted current through the system, from the ground to the station, and, by carrying an induction coil with a telephone receiver over the wires, we were able to follow in the direction of the ground.

My method is a modification of this. I divide the system into sections, and with auxiliary bus bars can test each section without putting out the lights. After locating the section I would try the inside wiring with the device shown in Fig. 2. This consists of an induction coil with a receiver connected to the fine wire terminals and a non-inductive resistance with an interrupter. The primary of the induction coil has screw clamps for terminals so that it can be connected to each side of the cutout. The resistance coil R is connected from the other wire to ground. By removing the plug or fuse strip the current will pass through the induction coil. If the ground is in the building there will be a heavy induced current in the receiver ; otherwise only a slight hum caused by the direct current. If the ground is in the building a few more such tests will easily locate the ground. Should the ground be found on the outside underground wiring it can be located without danger of producing fire ; so putting on a load at

* From the *Electrical Engineer* of New York.

Digitized by Google

the station the indicators will show which feeder it is near. A junction-box can now be opened knowing that not more than one other will need be.

The first thing I do after opening the box is to test the feeder for ground, disconnecting of course. If it is in the feeder I disconnect both in the station and junction-box ; then connecting the terminals together in the junction-box I measure by the ordinary sliding-bridge method, as shown in Fig. 3. This is simply a Wheatstone bridge, and the point in the wire loop where the galvanometer is connected when the needle comes to rest will divide the loop just as the ground divides the feeder.

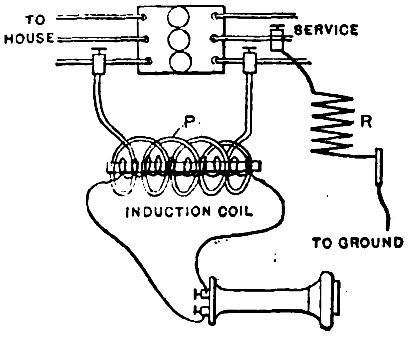

Fig. 2.

Should the ground be in the mains I use the same method as in inside testing, only using a heavier interrupted current, since the ordinary current is heavier. After locating the main and disconnecting so that it feeds from one end only, I put as heavy current through the ground as is safe without burning the smallest service, should the ground be in it. I now measure the voltage across this load and simultaneously at the services. The voltage across the load will be the same as that of the two services on each side of the ground. This is shown in Fig. 4. A, B, C, D, E, F are ser-

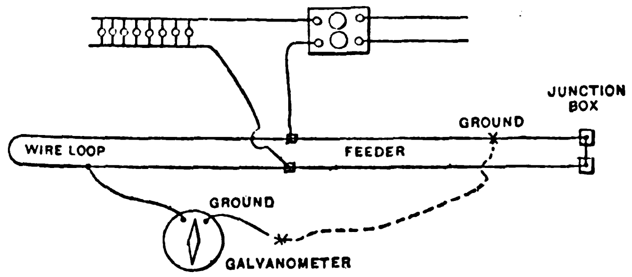

Fig. 3.

vices ; the voltage at M across the resistance is the same as at F and possibly a little less than at E since the current in passing through to the ground and back to K will produce an appreciable drop in the wire from K to the ground ; but the services F, G, H, will remain the same as M, as the testing is made when the load is light.

With the induction method 5 amperes is a large current and usually 2 or 3 is enough, depending on the normal current in the line. If the ground be in a cord or fixture this current will blow

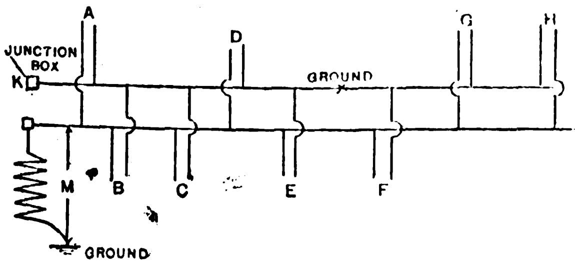

Fig. 4.

the fuse without any danger of fire, I do not advise a lamp bank for a testing resistance as it will attract attention, while a non-inductive resistance coil will give the appearance of connecting a telephone on the line "to hear the flow of the current. With overhead lines only the inside tests need be made as a good inspector usually knows his faulty spots and where to look first.

This may seem to be a long, roundabout method if the cut and try method has been used. But usually with two men, and often only one, I can locate the ground as soon as two men will by the "guessing process." Even if it took twice as long or cost twice as much, I would still advise the above method, I believe too much emphasis cannot be put on the importance of uninterrupted service either isolated or central station. One disconnected service costs ten times the apparent saving even if disconnected only for a moment, and it may cost a good customer. I believe the principal cause for the opinion of instability in electric lighting is due to the habit of employés indiscriminately disconnecting customers for testing purposes.

Of course we are avoiding grounds now by our better methods of wiring, both inside and out, than were employed five, or even three years ago ; still we have them, and that shows we cannot be too particular in watching our insulation resistance records. On arc circuits Rudd's method is the best ; but for Edison or other multiple arc systems I think a modification of Mance's method for measuring a resistance containing a potential difference, or else using two voltmeters at once, is to be preferred. I do not think much of measuring the resistance when the wires are idle but want the condenser effect.

COST OF ELECTRICAL ENERGY.

The following is an abstract of the discussion which has taken place on Mr. Crompton's Paper on the "Cost of Electrical Energy" (see *The Electrician*, April 27th, *et seq.*). Speakers who have returned their proofs revised have their remarks prefaced by an asterisk.

Mr. RAWORTH, in opening the discussion, said he imagined Mr. Crompton's was the most comprehensive Paper upon the question of works cost and management that had ever been laid before the Institution. In fact, it seemed to him to include very nearly the whole education of an electrical engineer. Mr. Crompton was endeavouring to show the possibility of reducing the cost of electricity to 3d. per unit to the consumer, and he arrived at the figures he had given them by first of all reducing the capital, and secondly by increasing the output, and thirdly by using better engines, boilers and dynamos. At first he (Mr. Raworth) thought the figures as to capital expenditure were scarcely justified, but on looking over the matter he found Mr. Crompton was perfectly justified, for at Bradford and Newcastle they already delivered eight units per sovereign of capital expenditure ; the next best were St. James's, six units, and St. Pancras, five units per sovereign. Then came Bournemouth, Westminster and Charing Cross, who delivered four and a-half, the Metropolitan, Kensington, and Liverpool gave four, and last of all came Preston and Oxford with two. Of course, it was too bad to try to apply the moral in these cases, because stations were so remarkably various. There was one very important point Mr. Crompton had made in connection with coal. It might be remembered that, some year or two back, Mr. Crompton put forward a table in which he connected all the prices per unit for coal expenditure by putting them through the sieve of their British thermal units and bringing them all up to one level, and showing what the cost per unit of coal would be in each station if the value were duly corrected. He (Mr. Raworth) then put out the hydrogen, which, although it counted perfectly well in the table, did not count in the boiler. He saw now that Mr. Crompton had fallen in entirely with his view, and had corrected his own views on that point. With regard to the boiler question, he quite agreed with Mr. Crompton, although it was quite contrary to what every boiler maker would tell them, that Babcock-Wilcox boilers did *not* give wet steam. Now he would go to the question of engine efficiency. Mr. Crompton was one of the first to put the theory of direct coupling into practice, and they owed him very great credit for the example he had shown in that direction. He could assure Mr. Crompton that they who had to build alternating current plants would have followed his example long since if it had been possible, but in the early days of the alternating current industry they could not get the money to do it, and in the second place they did not see their way to do it, because, as they all knew, they could not run an alternator at any speed they liked ; they had to run it at a speed which was in accordance with the periodicity of the system they had chosen. Therefore they had to find some other means of driving, and they took to rope driving, which had been pretty generally adopted, but they had found out—in fact, they knew all the time—that the sooner they could get rid of the ropes the better, because they were losing something like 6 per cent. all the time they were running—not 6 per cent. of the load only, but 6 per cent. solid loss. Therefore as soon as they could see their way to do it they would abandon rope driving and come on to direct driving also, so if Mr. Crompton would give them further statistics he hoped the alternating-current plant figures would come out very much better than they had done now. Coming to engine losses, Mr. Crompton was a great admirer of the Willans engine, and rightly so, for it had stood the industry in very good stead, and he himself admired it very much indeed. But when Mr. Crompton said the Willans engine was more efficient from the point of view of mechanics, he was under a wrong impression. He knew very well that the efficiency obtained was 89½ or 90, which was very good, but it was owing to the fact that makers of ordinary double-acting vertical engines never had the apparatus for testing their engines that the idea arose that this efficiency claimed for the Willans and Robinson engine was the top one. He could get—and anybody could get—from the ordinary vertical double-acting engine 92 per cent. ; it could easily be got, there was no trouble whatever about it, no special arrangements. The reason the idea had grown up that the Willans engine was so much more efficient than ordinary engines was that the ordinary engines which had gone through many and accurate tests had usually been horizontal

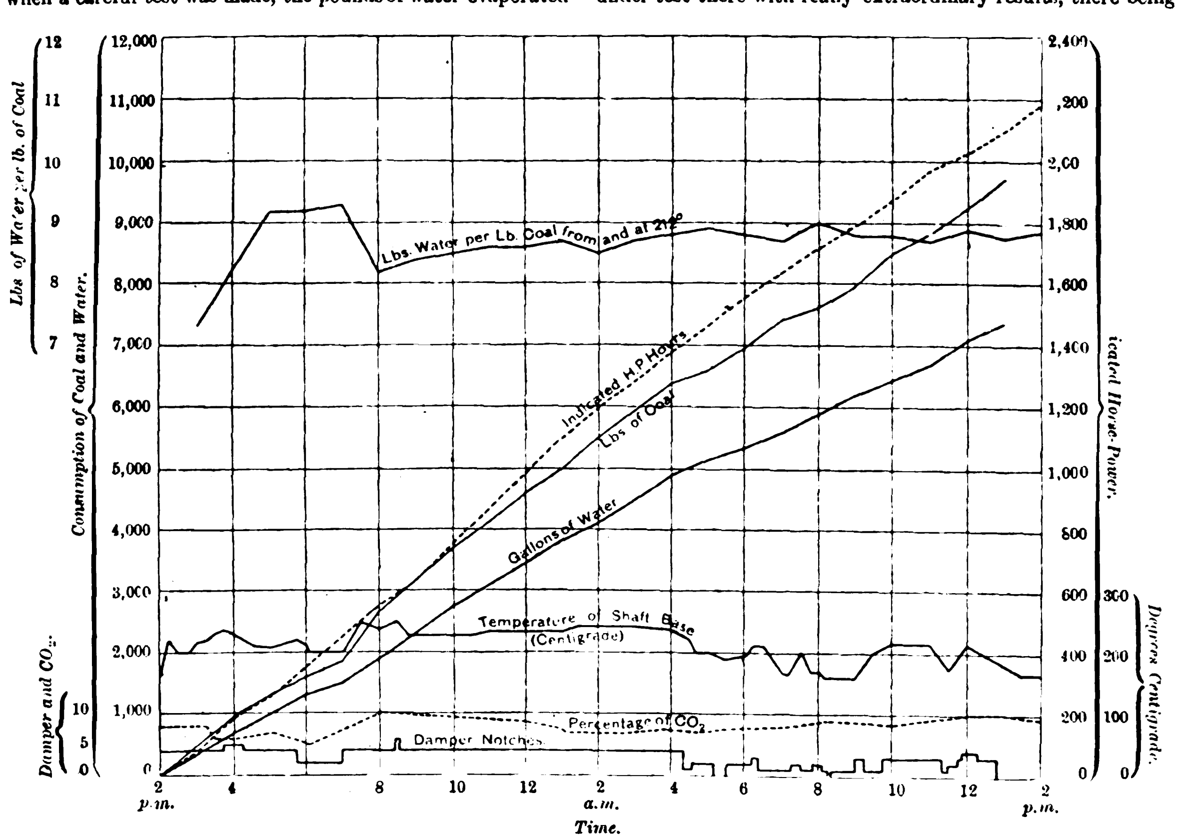
Digitized by Google

engines, and in those cases they had to deal with mechanical drag, a piston weighing tons, moving backwards and forwards at the rate of 500ft. or 600ft. a second, sliding on the bottom of a cylinder, and that made it almost impossible to get a higher efficiency, and made the Willans engine so much ahead of ordinary engines. But he would point out that the Willans and Robinson engine was extremely efficient on the down stroke only; on the up stroke it lost its efficiency, because when going back it was doing no power. Therefore, if they could make it double acting, probably its efficiency would go up to 95 per cent. He thought Mr. Crompton had fallen into one pretty serious error in regard to the efficiency of distribution where it referred to alternating-current systems. In central stations they simply took amperes multiplied by volts for their outgoing. As a matter of fact it was much less than that. The alternating-current systems were used in districts which were not to be compared with the districts where continuous currents were used. Taking Bournemouth as an instance, there were miles upon miles of wires in all directions; in fact, they could scarcely see from one house to another. Compare this with St. James's, where the work was not much different from lighting up a large hotel. Therefore, without large local knowledge it was almost impossible to form an accurate conclusion.

The discussion was then adjourned.

THURSDAY, MAY 10TH.

At the adjourned discussion on Thursday evening, May 10th, Mr. CROMPTON first drew attention to a diagram (*see* Figure) giving the results of a 24-hour test of a boiler at the Chelmsford power station. It showed that when a careful test was made, the pounds of water evaporated



per pound of coal rose to a little over 9; that was to say, the same boiler and the same apparatus which on the year's run come out at 5·2, under the careful conditions of the test got as high as 9. That was the class of test he recommended to be taken at frequent intervals in stations in order to enable the engineer in charge to know what their plant was capable of doing on the 24-hours' cycle. There was no doubt that, if at Chelmsford they took the same pains throughout the year as on that particular occasion, they would get for every day in the corresponding period of the year as good a result as on that occasion.

*Major-Gen. WEBBER said he was at a loss to know upon what system, especially in the metropolis, Mr. Crompton had framed his estimates. For instance, in Kensington, the three companies had a capital expenditure of £3 per lamp. Did Mr. Crompton believe that he was going to reduce that £3 to £1. 6s.? Did he forget that, of the 60 miles of streets which would be the ultimate area which would have to be lighted in Kensington, only about 4 miles had mains along both sides? Did he forget that the total plant of the three companies had only a capacity of 2,300 E.H.P. output, and did he believe that when that reached 13,500 E.H.P. output, which was the probable requirement of Kensington in a few years, he would then have come down to a capital expenditure of £1. 6s. per lamp? He (the speaker) did not think he did, and therefore wished to ask him where his ideal station would be. The speaker then criticised the mode in which the author of the Paper had collected his data, and the use he had made of them. The speaker was of opinion that the engineers who supplied data should have a hand in the compilation of the tabular statements. Chelsea was one of the most mixed stations in this country. The Paper which he (Gen. Webber) read two years ago described that station, and stated that, while accumulators were the main source of supply, there was also a distribution between transformer-motors and accumulators, showing a maximum loss of 30 per cent.; the supply by transformer-motors having a loss of very little more than 15 per cent., and the direct-current portion of the supply having a loss between the terminals of the dynamo and the consumers' terminals of 10 per cent. Therefore he did not think it was quite right to include the Chelsea system as not being one of those mixed systems purposely left out of the report for purposes of comparison. He thought the term "efficiency of distribution" was altogether a misnomer. It might be efficiency of copper. If Mr. Crompton had left out all the information regarding companies with which he was not acquainted, no one would have complained. He sympathised greatly with the engineers of the stations dealt with, because those of them who declined to fill in the returns must have disapproved of its form.

*Mr. MARK ROBINSON said: He hoped Mr. Crompton's prediction as regards the 2·5 of coal per unit might be realised. The prediction rested on three factors, amongst others; first, the evaporation by the boiler of 12lb. of water per pound of coal; secondly, the consumption by the engine of only 12lb. of steam per indicated horse-power hour; and thirdly, only a small amount of friction. With regard to the boilers, all he would say was that the figure of 12lb., or 10lb. in ordinary work, including all losses, was beyond the present practice. With regard to the dryness of steam from water-tube boilers, his own Company had lately taken up a water-tube boiler, from which they hoped great things, and from which they knew they got dry steam. They had had one under test there with really extraordinary results, there being about ¼ per cent. of moisture only. Mr. Crompton said his experience of Babcock boilers was that they were able to force them very much beyond their original capacity, and they had still given dry steam. They had had just the same experience with the Niclausse boiler, which at its proper rate of evaporation, gave less than ¼ per cent. of moisture in the steam. It was then worked at considerably more than twice its rated capacity, and still gave less than 1 per cent. of moisture. They had tested a Babcock boiler about the same time, and with practically the same result. The figures mentioned for the consumption of steam (12lb.) had been reached, he believed, by the Sulzer engine. One could wish that the results had been corroborated by concordant results from a good series of progressive trials, or, at least, that they had been the means of many trials. The undoubted competence of the observers in the case of the Sulzer trials commanded, however, their fullest respect and acceptance. Mr. Willans's best experimental figures at Thames Ditton were about 12·8lb., and the best guarantee they had ever given was 13·5lb. for a mill engine of 500 I.H.P., though this probably allowed a very good margin. He had no doubt they could, by carrying expansion much further and by jacketing to the utmost and carrying out every refinement possible, bring the high-speed engine down to the same figure as the Sulzer engine; but in doing so they would have to make a bigger engine, with larger cylinders and pistons and more ring friction, and, of course, at much more cost. With a larger ring friction they would get smaller brake efficiency in the engine and smaller combined efficiency in the plant. He was afraid the combined efficiency of 86 to 88 per cent. upon which Mr. Crompton relied would not be forthcoming. That was the point he wanted to bring out; they could not eat their cake and have it too. They must

Digitized by Google

not take the smallest steam consumption *and* the smallest friction, and expect to get both in the same engine. Mr. Raworth at the last meeting said the brake efficiency of the Willans engine was 89½ to 90 per cent., and he went on to say that every other vertical engine had the same or more, and he named 92 per cent. That was very well, but he would like to know how it was arrived at. He did not think it was safe to say, because one had taken a friction card with an engine running light, and it showed only 8 per cent. of the full power, that the brake efficiency was 92 per cent. In the case of the Willans engine it probably was so; but he thought the Willans engine differed in that respect from ordinary engines. Mr. Raworth stated that if the Willans engine were double-acting it would have considerably less friction in proportion to power developed; but that meant ring friction, and ring friction was practically constant at all loads. There were four principal kinds of friction, it appeared to him, which an ordinary engine suffered from. In the first place, there was the friction of rings—piston rings—and valve piston rings. That certainly was practically independent of the load. Then, secondly, there was slide-valve friction, which in most engines rose rapidly with the load; but from that the Willans engine was of course exempt. Thirdly, there was the bearing friction, which, when the brasses were bathed in oil, seemed by the trials they had made not to rise with the load, but which they believed, in the case of double-acting engines, or, at any rate, where the bathing in oil was not so complete, *did* increase with the load. Fourthly, there was another friction loss, increasing with the load, where the pressure on the brasses was not all in the same direction, but involved alternate pull and push, as in ordinary engines—what the Americans called "lost motion"; of its rate of increase they knew nothing, but they believed it existed, and at any rate the single-acting engine was free from it. Thus it would appear that the single-acting engine had only sources of friction which were approximately constant, whereas that with which Mr. Raworth compared it had also causes of friction which increased with the load. Therefore, he was not able to accept friction cards as conclusive upon brake efficiency. The mean of a number of engine tests made on Willans engines which were new and stiff, and which would certainly give better results afterwards, came out at 90·6 brake efficiency. Those tests were made with a brake arranged on what was usually known as Mr. Halpin's plan, and they believed the figures were reliable. Mr. Crompton had made an excellent practical suggestion in one small matter, the use of a pressure gauge on the steam chest. If people knew how useful such an arrangement was they would always use it.

Mr. W. GEIPEL said he hoped to show that Mr. Crompton had been altogether too modest. He (Mr. Crompton) said, in speaking of the item of first cost, "we engineers have nothing to say in controlling these figures." He (the speaker) did not for one moment agree with this. The reduction of the cost of electricity supply stations was very largely indeed the business of engineers. In his opinion the present high price of electric supply was due mostly to an insufficient consideration having been given to this question of first cost. It was certainly not always judicious to incur every possible expense in providing for saving in coal and labour and stores without regard to the consideration of outlay. For example, costly chimneys were frequently erected when a less outlay in this respect would suffice, or condensers and economisers were erected capable of dealing with the maximum load, the consequence being that a large portion was utilised but a mere fraction of the year. Was it not the function of an engineer to so lay out the capital that the cost of interest, depreciation, and the working expenses were together a minimum? Mr. Crompton did not say precisely how he arrived at his first cost of 2s. per unit sold per annum; but if his basis were the 20 per cent. load factor to which he alluded further on, his figures meant a cost of £175 per kilowatt. It was his opinion that the first cost might frequently be less than one-half this figure, not certainly on the low-tension direct-current system, upon which he feared Mr Crompton had based his figures, but with the more modern alternate-current system, using high-tension feeders, supplying by transformers a low-tension network. He did not see why the improvements which were being made in the efficiency, and the reduction of the cost of alternators and transformers, should not enable them in future to arrive at a figure of £60 per kilowatt under favourable circumstances. He was not so sanguine, however, as Mr. Crompton upon one or two points. A 20 per cent. load factor was not often recorded in central stations in this country. Even 15 per cent. was considered good. He did not see how coal could possibly be reduced to 2½lb. per unit, but believed 4lb. might be reached, even with English coal, which could be obtained at 7s. and less per ton, making the cost of coal 15d. per unit. He was afraid that the figure Mr. Crompton had given, namely, 12lb. of water evaporated per pound of coal, was one the attainment of which would gladden the hearts of legions outside the electrical profession. He was aware that, under specially favourable circumstances, with the best fuel and conditions, and deducting ashes, this result might be attained on occasion, but he had not yet found anything approaching this in practice, even under circumstances much more favourable than those which obtained in central station working. In fact, further on in the Paper, a lower figure, namely, 10lb., was spoken of. At the same time, there could not be a doubt that there was room for improvement, and perhaps he might be permitted to mention two methods of setting boilers which he had designed with a view to reducing the losses due to the radiation from boilers. One was applied to the Babcock-Wilcox boiler, which, as they were aware, was enclosed by a large amount of brickwork, absorbing, as Mr. Crompton pointed out, a proportional amount of heat. In order to reduce this he had introduced a thermal insulator in the form of an air-space in the middle of the side walls, so that the outer half did not absorb as much heat as heretofore. This setting had been applied to the boilers at the Huddersfield and other electricity works, and had, he understood, been since adopted by Messrs. Babcock at another place with good results. The other method related to cylindrical boilers of the Lancashire and similar types which he arranged as follows:—The gases, after passing through the boiler and under, were diverted into a main flue, which led on to the economiser; from this they passed by a large side flue round each boiler consecutively to the chimney; so that whatever number of boilers happened to be out of use at any time, they were kept warm by the waste gases from those in use. He did not agree with Mr. Crompton that the Lancashire boiler was unsuitable in all cases for electric lighting purposes, nor that its efficiency compared so unfavourably with other boilers. The comparison given between the marine boiler at Glasgow and the Lancashire by Bryan-Donkin was certainly unfavourable to the Lancashire, but of all boilers the Lancashire was most unsuited for burning coke. It would probably be found that with bituminous coal the results would be reversed. Mr. Crompton spoke of a difficulty in utilising the hydrogen constituents of the coal. Might he suggest that, provided there was an excess of the proportion of hydrogen above that required for combining with the oxygen already in the coal there should be no difficulty with a suitable furnace in utilising the heat of combustion? He thought it had been demonstrated that bituminous coal could be burnt under proper conditions without causing smoke, while the results of tests of the flue gases, so far as he knew, did not show unoxidised hydrogen to any extent. There was this advantage with the bituminous or flaming coal, namely, that the heat was less confined to the grate. In other words, it enabled a more gradual use to be made of the boiler-heating surface. At the same time, he quite agreed with the author that anthracite coal had many advantages. He merely pointed out that there were numerous districts in this country where bituminous coal could be used with far greater economy than anthracite or Welsh coal. The great point which accounted for the suitability of the Babcock boiler, was in the small quantity of fuel required for raising steam, which was largely due to the small proportion of water contained in the boiler. He was inclined to believe that there were cases where it would be advantageous to use a combination of Lancashire and Babcock boilers where bituminous coal was cheap, using the Lancashire continuously, and the Babcock for the top parts of the coal curve. He was sorry to see that Mr. Crompton recommended the use of boiler fluids, &c., to keep the scale and sediment from affecting the surfaces; he was of opinion that the boiler was not the proper place to effect the deposit of mud and scale. The better cure was the removal of the impurities from the water before it entered the boiler. The reserve power afforded by the forcing capabilities of the Babcock boiler was of enormous importance, for it enabled the passing over of the peak of the load curve with a smaller quantity of boilers, and though at the moment of forcing there might be some loss of efficiency, it was probably more than counterbalanced by the saving in steaming further boilers, to say nothing of the saving in capital outlay in having less boilers to provide. He was glad to see this forcing advocated by Mr. Crompton, and was of opinion that it might often be worth while providing blowing apparatus to be used during the heavy load period, which after all presented a mere fraction of the whole year. Mr. Crompton referred to the average efficiency of the existing alternating systems as 66 per cent., but this was largely due to the use of separate transformers. The result of banking transformers was, however, making enormous improvements in this respect, and in Mr. Crompton's table this was instanced by the 82 per cent. of the City of London Company. He was glad that Mr. Crompton advocated superheating the steam. He had for several years been an advocate of this practice, but instead of resorting to the use of superheaters, of which Mr. Crompton rightly points out the difficulty, why not evaporate the steam at a higher pressure, using reducing valves on each boiler? There was no difficulty in working a Babcock boiler at 200lb., and if steam at this pressure were reduced to 150lb. pressure in the steam pipes they would at once have approximately the 8 per cent. superheating mentioned by Mr. Crompton. The loss in the steam pipe was undoubtedly of the most serious nature, and every precaution should be taken to subdivide the steam pipes into sections controlled by valves, so that only that portion of the steam pipe which was absolutely necessary at the time being was used. Mr. Crompton spoke of the use of surface condensers, as entailing the working out of several very difficult problems connected with the thorough filtering of the oil contained in the exhaust steam. Why use oil in the cylinders at all? It was a common practice in the Mercantile Marine, and Mr. Raworth never had a drop put into his cylinders, condensing or noncondensing. This was a very simple solution of the difficult problem. He confirmed all Mr. Crompton said as to the wastefulness of direct-driven feed pumps. His attention was first called to this about six years ago, when he made two six-hour tests. Since those tests his Company had designed a pump driven by spur gearing from a high-speed engine, from which very much more economical results were obtained.

*Mr. SCHÖNHEYDER said: He had intended to make some remarks about Mr. Crompton's statement as to the poor efficiency of Lancashire boilers, but there were other gentlemen in the room who would make them better than he could. He would only say that, in making such a statement, Mr. Crompton ought to have put a note stating the rate of evaporation in pounds of water per square foot of heating surface per hour; without that it was impossible to say whether the boiler was economical or not. The other point to which he wished to refer was in respect of water-meters. It was evidently of great importance that the water should be measured for electric light stations, and Mr. Crompton had been good enough to refer to his (the speaker's) meter. Mr. Crompton stated that it had given him fairly satisfactory results. He (the speaker) had lately arranged improvements whereby all the seven rollers and their pins were entirely done away with, and he believed he had now got over all the difficulties in measuring hot water.

Mr. ROBERT HAMMOND said: They ought to be grateful to Mr. Crompton for his prophecy of a selling price of 3d. per unit. It had been said it was a pity that he had mentioned such a figure, because those outside would be distressed to find that whilst waiting for the 3d. they

were being charged 5d., 5½d., 6d., and so on. He did not share those views. He thought the more they could make outsiders feel that this industry had a basis whereon it could compete directly with every other illuminant, the sooner their fortunes as electrical engineers would be made. With regard to the 3d., however, it certainly was an alarmingly low figure; 3d. per unit on 5,000,000 units was £62,500 per annum; and perhaps Mr. Crompton in his reply would inform the members how many towns in England at the present time had gas companies with such a revenue. In all these comparisons they too often forgot the question of output. It was impossible with any justice to compare the costs of two companies without taking the question of output into consideration first and last. He thought the plan of finding out what the extra cost of the extra output was from one twelvemonths to another did give them a bit of a guide towards the soundness of the working cost of the works. If it were possible, having attained a certain output, whatever it might be, to increase it by 10, 15 or 20 per cent., with only an increase in cost of 2½, 5, or 7½ per cent., then those works would be in an extremely sound condition. Mr. Geipel referred to the average of some half-dozen or dozen of the companies in a certain list, and drew the attention of the members to the very great difference existing between the ideal figures of Mr. Crompton and the actual figures being obtained. There came in the question of output. The basis of Mr. Crompton's Paper was some huge concern. The next point was that Mr. Crompton omitted depreciation. Mr. Crompton's reply no doubt would be that he had made ample provision for maintenance. That was a doctrine he would very much like to hold, but he dared not, for he could not shut his eyes to the fact that even if there were no depreciation there was an "antiquation" element to be considered. Mr. Geipel said that possibly they might reach the ideal capital outlay of £60 per kilowatt. It happened that at Leeds, where they began with only 250 kilowatts last year, and where the success had been so abnormal that they would finish this with 900 kilowatts, their cost would be below £60 per kilowatt. If electricity was going to be supplied at 3d. per unit it must be by means of the by-products, or, what came to the same thing, by the uses of the plant in those hours, 21 or 22 very often out of the 24, when the lighting was not called for.

Mr. M'LAREN said that he was not an electrical engineer, but a maker of engines for driving electrical machinery. The question of the cheapness of the production of electric light depended to a very large extent upon the motor by which that light was produced. The crux lay in the coal consumption, and in order to reduce the coal consumption it was necessary to have an engine which would use a small quantity of coal for the power that was given off. Now, in the published tests of engines the information was very often incomplete, if not misleading. They very often read of the tests of particular boilers, and they were very interesting, so far as they went, but they did not afford engineers sufficient information to enable them of themselves to choose which was the best boiler for the purpose of driving an electrical machine. A boiler might give a very good result in evaporation when tested by itself and by the water that was pumped into it, and by the steam that was given off from it; but if that steam was largely saturated with water the evaporation which was ascertained by the test would be very misleading. On the other hand, there were engine tests which were conducted irrespective of the boiler which supplied the steam. Those tests might be very satisfactory, but if the engineer who was putting down an electrical installation was guided solely by the figures which were put before him in that way he might be very far astray when he came to put his boiler and engine down. The only true criterion was to test the engines in connection with the boilers they were intended to work with. The figures might look very pretty for the boiler and very pretty for the engine, but when they came to be tried together they might be very far out. With regard to the question of steam generators, he agreed with the author of the Paper in so far as the locomotive type of boiler was concerned, but he disagreed with him in regard to the amount of evaporation which he put down as the ordinary evaporation of a locomotive boiler. They had found in their own experience that the evaporation of locomotive boilers was a great deal nearer 10 than 7, at which it was put down in the Paper. They had had in tests of their own locomotive boilers as much as nearly 12 evaporated from and at 212deg. He had no hesitation in undertaking that in the ordinary way, with a well-constructed boiler, they could depend upon an evaporation of from 10lb. to 11lb. of water per lb. of coal from and at 212deg. The evaporation of many boilers, especially of water-tube boilers, with all due respect to Mr. Robinson, was in many cases an unknown quantity owing to the wetness of the steam which they frequently gave off. Then the Lancashire boiler was very much over-rated, because they found as a rule that the gases were generally discharged at 700deg. (?), necessitating the use of a very expensive economiser, for unless the boiler was accompanied by an economiser the efficiency as a steam producer must be very low indeed. He accounted for the great economy at Oxford by the fact of the engines being triple-expansion slow-running and surface-condensing. He thought it was a very great mistake to put down high-speed engines to drive electric plants. He did not expect that to go down readily, but he was quite sure, if he might be allowed to prophesy, that the future electric lighting engines would not be high-speed small engines. They might just as well put an express locomotive on with small cylinders and small wheels to drive the express trains, and run it to death. With regard to the cost of maintenance, they knew something about single-action engines; he was not speaking of any particular engines, but of single-action engines generally. He knew some makers of engines of that class of engine would undertake to keep them in repair at rates very far beyond what would be required to keep slow-running engines in repair, and it was in the maintenance as well as in the economical production of steam and the economical use of it, in his opinion, that the cost of electric lighting was going to be reduced.

Mr. M'LEAN said: Mr. Crompton had criticised the Oxford system in one or two points. He said that under the head of "Stores used in the Generating Works" the decrease had been very noticeable during the last few years of working, and in the case of Kensington Court it had reached as low a figure as 0·025d. per unit sold, adding that no doubt a lower figure would be reached as the output and load factor improved. In a note in *The Electrician* Mr. Crompton was reported to have said, in speaking of the efficiency of distribution, that the Oxford figures came in at a late period, but that the results were very encouraging; in fact, were almost too good to be true, especially in regard to the use of stores as shown in Table VII. In that table Mr. Crompton gave 0·03 as his ideal; Kensington Court had reached that low figure. Why should he discredit the statement that they had reached the figures given at Oxford, which were still 50 per cent. above his ideal? It was no argument that because no other station had got so low Oxford had not, and he was quite prepared to substantiate his statement. It might interest Mr. Crompton to analyse their sheet of daily working; it was 4ft. 6in. long. They were very small people down at Oxford, but they held the record in one or two items, and he was glad to have had the opportunity of coming there and substantiating his statements.

Mr. BURNETT said he was only in a position to speak on the boiler question. He did not think Mr. Crompton was quite right when he said, that in judging of the comparative value of fuels they should always remember that it was far less difficult to obtain a high boiler efficiency from steam coals than from those which contained a larger percentage of carbon in the form of coke. There must be a grate to suit the quality of fuel used. He sympathised with Mr. Crompton in what he said about the mechanical disadvantage of locomotive boilers, and he thought Mr. M'Laren slightly misunderstood Mr. Crompton in regard to that. He did not think he found fault with the efficiency of locomotive boilers, but with the difficulty of dealing with the low grates in putting in the fuel and banking the fires, and certainly the ordinary locomotive fire-box type was not the best. It was pretty well acknowledged that the Babcock and Wilcox boilers could do, and had done, good work with Welsh coal, and he thought the great radiation which Mr. Crompton feared, would not be serious in a range of boilers, but only with a single boiler. He did not think, however, that it had been established that they were the best for efficiency. When used with bituminous fuel they were certainly not the best. He was greatly surprised that Mr. Crompton had so lightly passed over the more or less difficult problem of cleaning the boiler. The next step boiler engineers must take must be to analyse the merits of their boilers at different speeds and rates of evaporation, just as Mr. Willans did with his engines.

The discussion was here adjourned until May 24th.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 4, 1894.

Electric Traction.—The New York Legislature at its closing Session passed a Bill offering a prize of $50,000 for the most economical system of street railway traction. The object of the Bill is to take up the recent sham competition of the New York City Metropolitan Traction Company, and it now awaits the Governor's signature. Mr. E. H. Johnson, well known in England in connection with the placing of the Edison patents there in the early days of electric lighting, has been experimenting during the winter with an electric street railway underground system, and has just made some of the details public. The system—the joint invention of Mr. Johnson and Mr. Robert Lundell, the inventor of the Lundell dynamo and motor—consists of short lengths of a centre contact rail, from which the car takes current by means of a sliding brush, and to which current is fed when contact is successively made by means of mechanism in underground boxes, which is actuated by an electromagnet in the bottom of the car. Each car has a storage battery to "pick up" when necessary the line current, and also for emergency use and to pass over crossings if thought desirable.

The "Goebel Defence."—The United States Circuit Court of Appeals for the Eastern District of Wisconsin has handed down an opinion in the Oconto lamp case which finally, it is thought, disposes of the celebrated "Goebel defence." The opinion refers to the struggle of the scientific world from 1854 to 1880 with the problem of the subdivision of the electric light, and states that the mind cannot readily assent to the assertion of Goebel that he had in the meantime solved the problem, and yet made no attempt to claim the benefit until after the Edison lamp had for years been on the market. Several patents taken out by Goebel are referred to, and the conclusion arrived at that it is unbelievable that one so careful of his rights with respect to trifling matters should evince utter disregard of his interests in a matter of such great moment as his alleged invention of the incandescent lamp.

CORRESPONDENCE.

THE RELATION OF CAMBRIDGE MATHEMATICS TO ENGINEERING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have generally made it my practice not to reply to reviews of anything I may write. If I do so in relation to your review of my lecture at the Institution of Civil Engineers, it is because I do not think your reviewer does justice to my university, not because I am in any way personally annoyed. Is it the fact that geometry is taboed by Cambridge mathematicians? Maxwell, you admit, used geometrical methods freely, and you might have added to the illustrations you give his book on heat wherein the subject is treated in the text geometrically, and the corresponding analysis is hinted at in footnotes. Lord Kelvin's method of electrical images is essentially geometrical, and from his work many other examples could be collected. Tait gives the theory of the damping of oscillations a geometrical form. To come to a humbler example, my own work whether on characteristic curves or on alternate currents, is more frequently handled by geometrical than by algebraic methods. Geometrical methods have at Cambridge a specially protected position. But my belief is that as a fact algebraic methods have been useful for discovery more frequently than geometrical. The work being once done it is often easy to cast it into a geometrical form. The point may be illustrated by a story which was current years ago at Cambridge. In old times the geometric methods of Newton were alone admitted in the Senate House. An eminent candidate had read the French Algebraic methods, but he dare not, under dire penalties, introduce them to the examiners. What did he do? He worked out his problems algebraically first and then translated his algebra into geometry. And that is frequently done in the larger world, discoveries are often first made algebraically, and are afterwards translated into geometry.

Mathematicians should, indeed, be ambidextrous—equally ready with algebra and geometry. If in my lecture I have rather insisted on the uses of the calculus it was because I thought that its methods were unduly feared and shunned by engineers, not because either I or other Cambridge mathematicians disliked or shunned geometrical methods.—Yours, &c.,

J. HOPKINSON.

A UNIVERSAL SHUNT BOX.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Perhaps you will allow me to point out that the slip referred to by Mr. Sullivan in your issue of to-day occurred only in the proof of the Paper and in the Press reports of this proof; it will not be found in the Paper itself, as already printed in the *Journal* of the Institution of Electrical Engineers.

May we not claim that, as it is much easier to divide in one's head by 10, 100, and 1,000 than by 9, 99, and 999, the slip points to another advantage possessed by the universal shunt-box?—Yours, &c.,

T. MATHER.

May 11, 1894.

METHODS OF MEASURING SELF-INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the letter from Dr. Sumpner, which you published last week, he is aggrieved that I do not mention to whom the first method I described of measuring self-induction is due, and then, with strange inconsistency, claims it for himself. I should prefer to describe it as Maxwell's method, modified by Dr. Sumpner. The method is such an obvious modification of Maxwell's that it seems to me hardly necessary to change the title. Dr. Sumpner attributes the second method—rightly, I believe—to M. Joubert.

The object of my Paper was not only to explain shortly these methods, which have been used for years in many physical laboratories both at home and abroad, but also to show in a simple manner how they could be applied to measure mutual induction, and to give an extension of Prof. C. Niven's formulæ.

There are those who, advisedly or not, desire to have their names associated with all the work they do. But, surely, in this case, where the method in question is identical with that of Maxwell, except that, instead of spending time in reducing the deflections of the galvanometer to zero, the obvious suggestion is made that two readings be taken, and the zero reading got by simple interpolation, it cannot be right to name the method after the man who introduces such a small modification.—Yours, &c.,

ALEXANDER RUSSELL.

Faraday House, Charing Cross-road, W.C., May 16, 1894.

IMPOSSIBLE PRICES

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have before me a report in a local paper of a lecture delivered by Mr. Raworth, of the Brush Engineering Company, at the Guildhall, Winchester, on Tuesday, the 8th inst., in which he is stated to have said, "He was aware of the objections as to the initial cost of fitting up premises with electricity, and he did not think under the most favourable circumstances it could be fitted into private houses for less than 17s. 6d. per lamp, but in the case of shop windows and in hotels it could be done for half the price."

Now, what I wish to point out to you, Sir, is this, that considering the enormous amount of jerry wiring, &c., which is being carried on all over the country at the present time, at a very cheap rate, by plumbers and others who really have no claim to know anything of our profession, is it not a mistake that a man representing a company of the standing of the Brush Company should get up in a Guildhall and tell the people of a country town that they can get their wiring put in at a price at which most assuredly it can only be done in large towns, and that under very favourable circumstances? Surely we ought to be able to look to our leading firms to keep up the good quality of work, otherwise the production of inferior work will seriously endanger the standing of our profession in the estimation of the public.—Yours, &c.,

H. D. PARMITER.

Manchester, May 16, 1894.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK IS NOW READY. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"INVENTIONS, RESEARCHES AND WRITINGS OF NIKOLA TESLA," by T. Commerford Martin, may be obtained from the Publisher of *The Electrician*, and a copy will be forwarded post free on receipt of 16s. 6d.

"HOW TO WIRE BUILDINGS."—Copies of this work, by Augustus Noll, will also be sent by the Publisher post free on receipt of 6s.

TENDERS ACCEPTED.—The tender of Messrs. W. and J. Robinson and Co. has been accepted by the Bootle Town Council for the supply and erection of the electric light installation in the public buildings for the sum of £3,224, subject to Mr. T. L. Miller, of Liverpool, being employed to superintend the installation.

Digitized by Google

TENDERS RECEIVED.—The Lighting Committee of the Wolverhampton Town Council recommend the acceptance of the tender of Messrs. Bailey, Pegg, and Co., of Brierley Hill, for the supply of 36 arc lamp posts at £5. 15s. each and five arc lamp brackets at £2. 15s. each.

——— Seven tenders have been received by the Lighting Committee of the Brighton Corporation for the supply and erection at the central station of two motor-alternators, with switchboards and instruments, and for the supply of 12 transformers and 60 meters. The highest figure is £5,147, the lowest £1,731. 17s. (?), the latter from the Electric Construction Company (Limited), which is recommended for acceptance. The tender of the British Insulated Wire Company (Limited), for supplying the alternating cable required for Preston and North-East Brighton, together with the necessary joints and disconnection boxes, at £3,579. 6s., has been also recommended for acceptance.

APPOINTMENT.—Mr. Arthur Ellis, A.I.E.E., has been appointed Clerk of the Electricity Works by the Southport Corporation to superintend the laying down of the cables and of the fitting up of the central station equipment.

VACANT APPOINTMENT.—The Corporation of South Shields require the services for a few months of an engineering draughtsman as assistant to the electrical engineer, for the purpose of preparing plans and generally assisting him. Some further particulars are given in our advertisement columns; and applications must be sent in not later than noon of Monday, the 28th inst., to Mr. J. Moore Hayton, Town Clerk, Court-buildings, South Shields.

LIQUIDATIONS.—A petition has been presented for the compulsory winding up of Marchant, Young, and Co. (Limited), and is down for hearing on the 23rd inst.

SALES BY AUCTION.—Mr. Bradshaw Brown announces the sale by public aution of the stock-in-trade and loose machinery which is to be sold by order of the receiver and manager in Woodhouse and Rawson United (Limited), at Cadby Hall Works, Hammersmith-road, London, W., on Tuesday and Wednesday, May 22nd and 23rd, at 11 for 12 o'clock. Further information will be found in our advertisement columns, and all particulars can be obtained of the auctioneer, Billiter-square-buildings, E.C., and the Estate Offices, Millwall, E.

——— Several important sales by auction are announced in our advertisement columns by Messrs. Wheatley Kirk, Price, and Goulty. On Wednesday next, the 23rd inst., at the North Stafford Railway Hotel, Stoke-on-Trent, the valuable freehold land, buildings, engines, boilers, machinery, and plant of the Union Foundry, Kidsgrove, Staffs., is to be brought to the hammer. The time fixed for the sale is 3 for 4 p.m. prompt. On Tuesday, the 29th inst., and following days, an important sale of new and secondhand machine tools, plant, electrical fittings, instruments, and apparatus will take place on the premises, 39, Commercial-road, London, E.

SALE BY PRIVATE TREATY.—One of the oldest and best known machine tool-making concerns is, owing to the death of a partner, offered for sale by private treaty by Messrs. Wheatley Kirk, Price, and Goulty, of whom full particulars can be obtained either at the offices in London or Manchester.

INSTRUCTIONS FOR WORKING PLANT.—The Brush Electrical Engineering Company has issued a pamphlet of instructions for working dynamos, alternators, "Brush engines," &c.

PERSONAL.—Mr. E. R. Dolby, C.E., desires us to state that he has been appointed consulting engineer to Messrs. C. H. Glover and Co., of the Hatcham Saw Mills, for the electric power transmission plant and crane to be installed at the mills. Mr. Dolby has also in hand consulting work for the London Missionary Society, &c.

REMOVAL.—Messrs. King and Co. notify that they have removed from Rosebank Electric Works, Edinburgh, to the Leith Electric Works, Leith. The telegraphic address is changed from "Electric, Edinburgh," to "Electric, Leith."

——— Messrs. Davis and Soper, agents to the Johannesburg Lighting Company (Limited), have removed from 6, Great Winchester-street, to 54, St. Mary-axe, London, E.C.

ALUMINIUM SOLDER.—A recent issue of the *Iron Age* of New York contains an article describing a series of tests of a new aluminium solder now being introduced by the Alsite Aluminium Company. Among the tests made were butt welds of sheets and plates which, under tension, showed the soldered joint to be so well made that rupture took place in every instance outside the joint. Strips connected by butt soldering were twisted in the vice without opening the seam, and soldered tubing has been successfully drawn recently. The surfaces to be soldered are cleaned by dipping in a hot solution of soda or potash, then dipped into nitric acid, rinsed in hot water and dried. Sometimes the surfaces are cleaned by filing the edges to be joined. The parts to be soldered are heated as hot as can safely be done without melting. During the entire operation the metal is kept as hot as possible, and it is completed when the solder becomes distinctly white or the aluminium assumes a reddish hue.

"SNOWFLAKE" COMPOSITION FOR INCANDESCENT LAMPS.—Mr. V. Fabris, of 171, Drummond-street, Hampstead-road, London, has patented a new coating for incandescent lamps. The composition, which is called "Snowflake," possesses, it is claimed, the advantage of diffusing the light in a softer and clearer manner than by frosting or other coatings. The process also lends itself to many pleasing varieties of patterns and designs. It is also claimed that greater strength is given to the fixing of the bulb to the rim of the lamp. A variety of lamps coated with the composition are on view at the above address.

MANGANESE.—A contract has recently been entered into between the owners of the Manganese Mines of Tchiatoura (Caucasus) and the firm of Messrs. G. Pincher and Co., of Hamburg, for developing the working of the Caucasus Manganese Mines. This firm obtain a monopoly for the sale to European and American steel works. The estimated output to be annually delivered will be about four million poods (pood = 36·1lb.).

THE BRISTOL TIME CHECK.—Messrs. King, Mendham and Co. have now ready an illustrated pamphlet giving full particulars and instructions for using the Bristol electrical time check. This price list can be obtained on application to the Western Electrical Works, Bristol. The check was fully described in our issue on January 12th last.

INDIAN TEXTILE DIRECTORY.—We have received from the publishers of the *Indian Textile Journal* a copy of their Directory of Indian Manufactories, recently published. The book will be found of service to those interested in the textile industries, and lists are given of managers, owners, &c., of the principal cotton spinning and weaving mills in India. The Directory is issued by the publishers at 27, Meadow-street, Fort, Bombay, price 7s. post free.

THE JOURNAL.—Part III. of the *Journal* of the Institution of Electrical Engineers is now ready, and contains Papers by Mr. W. M. Mordey, Prof. W. E. Ayrton and T. Mather, and Prof. W. E. Ayrton and C. S. Whitehead, with full reports of the discussions thereupon. Copies can be obtained of Messrs. E. and F. N. Spon, price 3s.

FOREIGN EXHIBITIONS.—The *Moniteur Officiel du Commerce*, of Luxembourg, announces that a labour exhibition is to be held in that city from April to September, the principal object being to make known the different types of improved small motors, machine tools, and tools and accessory apparatus used in the different trades in the smaller industries, as well as the products made with these instruments.

——— An international exhibition of machine tools driven by electricity is, according to the *Bulletin du Musée Commerciale*, being arranged for by the Hungarian Commercial Museum in conjunction with an executive committee nominated by the Hungarian Minister of Commerce. This exhibition was to be opened in May, and is to remain open until the end of September.

——— The mining exhibition which is to be opened at Santiago in September is to be divided into eight sections, including motor machines, electricity, mining machinery, mechanical preparation of ores, metallurgy, chemical industries, statistics and plans, and products of the working of mines and metallurgy.

GAS AND ELECTRICITY.—At a meeting last week of the Liverpool Gas Fittings Company, the Chairman mentioned that some years ago, when electricity was coming to the front, they altered their Articles of Association to enable them to supply fittings for the electric light. Had they not done so they would have lost a good deal of business which had lately come to them. They were constantly getting orders for electric light fittings and that was one reason why they had been able to maintain their dividend (10 per cent.).

ASHTON-UNDER-LYNE.—At the last meeting of the Town Council a Sub-Committee was appointed to consider the question of erecting an electric lighting central station in connection with a refuse destructor. The Corporation obtained a Provisional Order in 1892.

AYR.—The Town Council on Monday agreed by a majority of 10 to 7 to adopt a plan prepared by Mr. Robert Hammond for the introduction of the electric light, the estimated cost being about £15,000.

BARKING.—New public offices are being erected for the Local Board, and the question whether gas or electricity should be adopted for the lighting was discussed at the last meeting, and, notwithstanding the advantages offered by the electric light, the question of cost was made the first consideration, and it was decided to use gas.

BRECHIN.—At a meeting of the Town Council on Thursday last week, Mr. Jamieson said that Messrs. Ferguson and Eggie, and himself, had inspected the Coatbridge electric light station, with which they had been highly pleased. He moved that the Town

Digitized by Google

Council apply for a Provisional Order, but although some discussion ensued no decision was come to. During the discussion it was pointed out that unless something was done by the Local Authority a private company would apply for a Provisional Order, and any opposition the Council had then to offer would have comparately little weight owing to their not proceeding in the matter themselves.

BOLTON.—At a meeting of the Gas and Electricity Committee of the Town Council it was decided to have a scheme prepared by the electrical engineer setting out the terms and conditions upon which arrangements may be made for the hire-purchase of electrical fittings by consumers from the Corporation's mains. Excellent progress is being made with the works, and Messrs. Siemens Brothers and Co. have begun the laying of the electric lighting mains.

BRIGHOUSE.—The consent of the Town Council has been asked for the obtaining by a proposed local company of a Provisional Order to take over the plant of Mr. A. B. Brooke, and to supply electricity in the borough, but at their meeting last week the Council decided to withhold their consent.

CAMBERWELL.—The Vestry have resolved to adhere to their determination to compel the London County Council to put all wires for fire stations underground. The County Council, from motives of economy, desire to place the wires overhead.

CARDIFF.—Mr. W. H. Massey, the electrical engineer to the Cardiff Corporation, has presented a report on the progress made with the electric lighting works. He states that the laying of mains and street work generally was practically complete, and that the machinery would soon be all in position. It has been decided by the Corporation to prepare a pamphlet setting out the scale of charges for electric current and bringing before possible consumers the advantages to be derived from adopting the electric light.

CARLOW.—It is stated that Major Alexander, of Milford House, Carlow, has purchased from the receiver of Messrs. J. E. H. Gordon and Co. (Limited), the plant, &c., of the Carlow Electric Lighting Company.

CHURCH LIGHTING.—An additional 200 lights is to be added to the installation at the Marylebone Presbyterian Church, Upper George-street, London, W., the order being placed with Messrs. Rashleigh Phipps and Co.

COVENTRY.—Mr. H. F. Tulloch held a Local Government Board inquiry last week into the application of the Coventry Corporation for permission to borrow £20,000 for the purpose of the electric lighting of the city. The Town Clerk and Mr. Robert Hammond, the consulting engineer, supported the application, which was not opposed. The Electric Light Committee have reported to the Town Council that they have approved the plans and specification of the proposed electric lighting station, and have ordered that advertisements inviting tenders be issued. 8d. per unit is the price fixed for lighting currents. 8d. per unit is the price fixed upon for lighting current.

DUNOON.—The Burgh Commissioners are contemplating the introduction of the electric light at the Castle Gardens this summer, at an estimated cost of between £400 and £500. The matter is to be finally decided at an early meeting of the Commissioners.

DERBY.—The Electrical Exhibition was opened on Monday last by the Mayor, and is held under the direction of the Electric Lighting Committee of the Town Council. The original idea emanated from Mr. W. H. Marsden, J.P., the Chairman of the Committee, but was not at first received with much enthusiasm; however, in the fulness of time, and by diligent application on Mr. Marsden's part, those who originally opposed the holding of the exhibition were brought to view the idea with favour. A catalogue has been issued, consisting of nearly 70 oblong quarto pages, giving a short history of the Electric Lighting Order for Derby, and the progressive steps taken to bring the scheme to a successful issue. A description is given of the central station, and the plant therein installed. The advantages of the electric light are set out in a popular way, and the list of exhibitors is a sufficient guarantee that the exhibition is not wanting in support from the contractors for the supply of electrical fittings and apparatus. At the opening ceremony the Mayor was surrounded by the leading citizens of Derby, and Mr. J. E. Stewart, the engineer and manager of the electric light works, Mr. W. H. Marsden, and several others, had an opportunity of clearly demonstrating to visitors the advantages electricity offers over all other illuminants for public and private purposes. Messrs. W. T. Glover and Co., C. A. Parsons and Co., Crompton and Co., W. T. Henley's Telegraph Works Company, the General Electric Company, Siemens Brothers and Co., all occupy prominent stands, and the Edison-Swan Company, exhibit a large variety of lamps of all candle-powers, fittings, &c. Altogether the exhibition promises to be a great success.

EDINBURGH.—The Lord Provost's Committee of the Town Council have recommended that the electric light be extended to Fountainbridge.

GEORGETOWN (BRITISH GUIANA).—At the annual meeting of the Georgetown (British Guiana) Gas Company (Limited), held on Tuesday, the Chairman said that the Georgetown Town Council first of all lighted a portion of the public lamps by electricity instead of gas, which accounted for the reduced dividend on last year's working. Since then the electric light has been entirely substituted for gas in the remainder of the public lamps. The Gas Company's outlook was, therefore, described as "gloomy."

ETON.—The Local Board have appointed a committee of five members to meet a sub-committee of the Windsor Town Council to consult on the electric lighting question, the last named body having received a numerously-signed memorial urging that prompt progress should be made in the supply of the electric light.

FOLKSTONE.—The question of the electric lighting of Folkestone has been before the Corporation in one form or another ever since April, 1893, and on April 6, 1894, a resolution was passed by the Corporation approving of a scheme which would cost £35,000. There has been considerable opposition on the part of the ratepayers to the expenditure of so large a sum, and at a special meeting of the Corporation, held on Thursday last week, it was decided by 9 votes to 6 to rescind the resolution previously arrived at. The original resolution under which the above decision was come to was proposed by Councillor Hall, and seconded by Alderman Banks, a director of the gas company. Subsequently the Mayor made a lengthy address on the subject, in the course of which he said that 90 per cent. of the ratepayers, although in favour of the electric light, were against the heavy expenditure involved. A Mr. Baker, in the course of the discussion, mentioned a scheme under which he was prepared to light a similar area to that proposed by the expenditure of £35,000 for the sum of £12,000, but a resolution that Mr. Baker be asked to submit his scheme to the Corporation was lost.

GUILDFORD.—The Corporation have not yet come to an agreement with the promoters of the electric lighting scheme respecting the period at which the Corporation should have the option of purchasing. The Corporation suggest 30 years, but the promoters, while originally stipulating for a longer term, have accepted a suggestion from the Board of Trade that the period should be 35 years, and the Board of Trade propose to grant an order on these terms. At the last meeting of the Town Council a resolution was passed that the Corporation were not prepared to consent to the grant of the order upon these terms.

HERTFORD.—The Town Council have had under discussion further information with regard to the proposed scheme for electric lighting. Information is being collected as to the charges to be made to consumers, and the Electric Lighting Committee are ascertaining the amount of support likely to be accorded to the scheme. The annual cost of gas for the lighting of the town and public buildings amounts to about £500, and it is contemplated that the electric light can be adopted within this figure.

JOHANNESBURG.—Our contemporary, *South Africa*, in its last issue contained an account of an interview with Mr. W. F. Lance, who is in this country on business in connection with the Johannesburg Lighting Company, of which he is Managing Director. Mr. Lance said in the course of the conversation that the demand for the electric light was rapidly growing, and he was endeavouring to arrange for the extension of plant.

LONDON COUNTY COUNCIL.—At the last meeting a report was submitted from the Highways Committee as to the feasibility of providing for the lighting of Westminster and Waterloo Bridges by electricity, apart from the question of similarly lighting the Victoria Embankment. The Committee stated that they had come to the conclusion that, in view of the very large extra expense the establishment of a separate installation for the two bridges would involve, it was not advisable that the course indicated should be adopted. The drawings for the generating station were approaching completion, and it was anticipated that the installation would be completed in time for the Embankment and the bridges to be lighted by electricity next winter. The Committee had still under consideration the question of the positions in which the lamp-standards for the Embankment will be placed; but in the meantime the other work could be proceeded with. The report was adopted by the Council.

LARNE.—The Town Commissioners on Friday, after some considerable discussion, ultimately passed the draft agreement between themselves and Messrs. J. E. H. Gordon and Co. for the lighting of the town by electricity.

MORECAMBE.—At the last meeting of the Sanitary Committee of the Local Board reports were received from the Surveyor and from the Medical Officer on the subject of an alleged nuisance at the generating station of the Morecambe Electric Light and Power Company (Limited). The Surveyor states in his report that it is his opinion that the nuisance is the manufacture of gas by the Dowson apparatus. The Medical Officer's report is to the same effect, and after careful consideration it has been decided to take proceedings.

Digitized by Google

against the Company unless the nuisance is at once abated. It is only fair to the Company to say that they have not yet had an opportunity of placing their views before the Committee; this opportunity is to be offered to the Secretary and Engineer at the next meeting.

NEWCASTLE.—The extensive premises of Messrs. James Coxon and Co. are now lighted throughout by electricity, the firm having undertaken the work with their own staff. Considerable extensions have recently been made.

NORTHUMBERLAND COUNTY ASYLUM.—The gas plant at the Northumberland County Asylum requiring renewal, the Visiting Committee have had estimates submitted them, showing the cost of renewing the gas works, and of supplying an electric lighting plant respectively. The total cost of new gas works, including boilers required for steam power for the new laundry, was estimated at £5,060, and the estimated cost of an electric lighting plant, including the same provision for the new laundry, was £7,275. The Committee, after some discussion, decided in favour of adopting the electric light, and have recommended it for the approval of the County Council.

PORTSMOUTH.—The Town Council have adopted the recommendation of the Electric Lighting Committee that the new electric lighting station be not insured, on account of the excessive premiums required by the insurance offices. Hydrants are to be provided at a cost of about £150, although it was said to be almost impossible for a fire to occur at the station.

ST. PAUL'S, COVENT GARDEN (LONDON).—The Charing Cross and Strand Electricity Supply Corporation (Limited) have applied to the Strand District Board of Works for their consent to the Corporation's application to the Board of Trade for a Provisional Order empowering them to supply electricity within this parish.

WEST HAM.—The Highways and Parks Committee of the Town Council have considered a proposal made by Councillor Hunns to advertise for a practical electrical engineer to advise the Council on the carrying out of the West Ham Electric Lighting Order of 1892, but, having given the matter careful consideration, the committee ultimately decided to recommend that the Town Clerk be directed to take all necessary steps to preserve the powers conferred on the Council by the Order, but that, owing to the outlay involved in the erection of the new sewage outfall works, no further steps be taken in connection with the electric lighting scheme for the present. It has been decided to invite tenders for lighting the Public Hall and Library, and the lamps in front of these buildings by electricity, the plant to be installed on the Public Hall premises.

WHITEHAVEN.—At the meeting last week of the Trustee Board the Chairman gave some figures showing the pecuniary results of lighting the town by electricity. He said that the total cost for the year had been £1,080. The revenue collected was £207, leaving the cost of public lighting for the year at £872, about £12 less than the cost for the preceding year, when the town was lighted by gas. He estimated that the cost of the public lighting during the coming year would be rather more, but it would then be considerably less than the average cost of gas for the last ten years, in addition to which the town was now considerably better lighted than it was formerly. It was remarked that for lighting the town twenty years ago the Gas Company were paid £1,990.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

May 3, 1894.

8,815. L. MOND and R. L. MOND. London. Improvements in electrolytic cells.

8,823. J. A. L. DEARLOVE. London. Improvements relating to the transmission of signals through telegraph lines and cables.

8,825. THE ELECTRICAL INSTALLATION COMPANY (LIMITED) and E. L. O'BRIEN. London. Improved means for conducting electricity through table-cloths, carpets, and the like to electric lamps and other electrical devices.

8,835. W. J. STILL. London. Improvements in the electrical propulsion of cars.*

8,838. J. PILLISCHER. London. Improvements in fuses or cut-outs for electric lines.

May 4, 1894.

8,845. J. L. PHIPPS. Oxford. Harness collar for carrying the electric light on harness.

8,895. F. KING. London. Improvements in or connected with secondary or electric storage batteries.

8,896. A. JOSEPH. London. Electrical apparatus for preventing collisions and other accidents on railways.

8,917. H. ALEXANDER. London. Improvements in or in connection with apparatus for the electro-deposition of metals.*

May 5, 1894.

8,924. C. LANGSTONE, B. YOUNG, and J. A. EWINS. Birmingham. Self-contained electrical generating apparatus and driving mechanism.

8,972. F. GRIFFIN. London. Improvements in or relating to secondary batteries.

8,976. W. S. SEATON. London. Improvements in submarine telegraph cables.

May 7, 1894.

8,982. T. B. GRANT. London. Improvements in dynamo-electric machines.

5,025. SMITH. Electric rail or tramway systems.

5,271. BROWN. Electric railways.

5,273. BARKER (Lawrence Electric Company). Electric railways.

COMPANIES' MEETINGS AND REPORTS.

Western and Brazilian Telegraph Company (Limited).

The twenty-seventh ordinary general meeting of this Company was held yesterday (Thursday) at Winchester House, Old Broad-street, under the presidency of Mr. W. S. Andrews.

The SECRETARY (Mr. R. M. Cunningham) read the notice convening the meeting, and subsequently the minutes of the previous ordinary general meeting.

The CHAIRMAN: Gentlemen, I presume that, as usual, you will take the report as read. We first of all have to deal with the receipts, and for the half-year ended December, 1893, they amounted to £80,338. 18s. 3d., as compared with £86,954. 11s. 3d. for the corresponding period, the difference being a diminution of £6,600. Remembering the state of things that existed during the half-year under review in Brazil, and what was to be expected, and what has actually happened, the receipts are very satisfactory. The international telegraph traffic with Brazil was completely suspended from September 6th to 20th; the internal traffic from September 6th to 18th; Santa Catharina was stopped for many months, and messages at various times were interdicted between Pernambuco

Digitized by Google

and Rio, and with the State of Parana; with Bahia between February 23rd and 25th, and from March 4th to 15th between all parts; for a week with Rio Grande; and then for international traffic with stations south of Rio and between Brazil and the Plate from April 9th to 13th. That is a pretty long catalogue of interferences with our business, and I think it justifies our course in not declaring a dividend last time, and shows you the risks that were being run during this period by your enterprise. I have stated that there has been a diminution of £6,600, but the remarkable point about that is this—that, in spite of all these circumstances there has not been a loss of traffic. On the contrary, we have actually transmitted during this period more traffic than in the corresponding period of the previous year, and we should, as you will have seen, have even transmitted still more but for these inhibitions. Now, how is it, with this increase of traffic, that we have earned less money? It arises from a circumstance which you are all pretty well acquainted with—namely, the unfavourable exchange prevailing in Brazil. In fact, the exchange during the period ended December, 1893, reached the lowest point ever recorded. The average, for instance, in the corresponding period of the previous year was pretty low—12d., but during this particular half year which we are now reviewing the average amounted to only 10¾d. I am sorry to say that the record of lowness is being surpassed at the present time, because the state of exchange now shows a still further reduction. Talking of the state of the exchange and of these fractions of pennies does not convey a very clear idea to the shareholders, but translated into plain language it means this—that, as compared with the par of exchange, we lost £20,715. 12s. 10d., and that the Platino Company lost during the year £16,563. 0s. 9d. Now you know that the net receipts of the Platino Company come to us in the shape of dividend. Taking these two sums together they amount to £37,278. 13s. 7d., or another 2½ per cent.; in fact, you would have got 5 per cent. instead of 2½ per cent., but for this exceptional state of the exchange. I have a word or two to say about that presently as respects traffic, but meanwhile I will go to the expenses. The expenses under abstract A were £19,003. 7s. 8d., showing, compared with the expenses of the corresponding period of the previous year, a small reduction of £45. 13s. There are eight items of increase and five items of decrease. It is of no use labouring the matter, because the difference is so very small. There is, however, a staff increase in Brazil of £955. 3s. 8d.; and there are two items, travelling and furniture, which show a reduction of £1,000. On the whole, therefore, there is a slight reduction. It is quite true that there is an increase of £955 in the staff, which means a permanent expense as to a certain portion of it, but I shall surprise you, I think, when I tell you that, in spite of all the competition we are subject to now, and in spite of the circumstances I have mentioned, there is an increase in the number of international words transmitted. There is no loss of traffic even upon that, but there is an increase, although the increase is insignificant as compared with the augmentation in the messages exchanged in Brazil from station to station—what we call the Brazilian internal traffic. Although there has been a pretty constant augmentation in this traffic for a large number of years, the amount of it during the half-year under review was exceedingly large—in fact, it would not be out of place to use the word "immense," because if we add the number of the internal words transmitted to the number of the international words transmitted we have actually done no less than 52 per cent. more work. Unfortunately, the amount received for these messages per word is extremely small. I suppose that we can scarcely expect that such a very large traffic will continue, notwithstanding the fact that there has been constant progression in it, but there is one very satisfactory point in connection with this large volume of business, namely, that it has been shown that our staff and other arrangements, made at great expense for working the loops, have been well calculated, and that the capacity of the line is such that we have been enabled to deal with this enormous amount of business. I may tell you that during this December half-year we transmitted on our lines upwards of two million words, exclusive of service messages. If, consequent on the restoration of order in Brazil, the expected development of commerce, and consequently of communication in relation to commerce by the telegraph should take place, the circumstances I have just named show convincingly that the Company will be capable of dealing with any increase with its present staff, and dealing with it in a very satisfactory way, because I may mention that the average speed with which our business has been interchanged with Brazil has been eminently satisfactory all the way through. Under abstract B, shipping, the total is £9,381. 19s. 5d., and as compared with the corresponding period of 1892, that shows the small increase of £266. 10s. 8d. That is owing to the fact that the "Viking" was out of commission in the corresponding period of the previous year for some 17 weeks, and that there was a remnant of expense on account of the "Norseman," which came into that year. The most accurate way, I think, of looking at our shipping expenses will be, not to take a particular half-year as compared with a particular half-year, because the half-years vary considerably, but to take average of five years, and that is what I have done for the purposes of comparison. I find that taking the five years the average annual cost of our ships has been £24,482, or £12,241 per six months, with which our £9,381. 19s. 5d. now compares not unfavourably; and it must be remembered that a further economy will be secured in reference to the outlay that appears here in the accounts of the "Viking." Under abstract C, the expenses in London, there is a reduction of £210. 15s. 2d. That does not quite exhaust the financial position in the corresponding period of the previous year and this year, because in the corresponding period there was an expense of £1,283 for duplex, and repairs on the "Viking," which had been nine years on the coast, and required an outlay of £3,859. Our cash outlay this half-year has been relieved of those items. The result of all this is that after setting aside £5,000 to the reserve fund, and £7,073 to the debenture redemption fund, and allowing for the credit of £7,679. 4s. 7d. brought over from last half-year, and £9,233. 15s. received from the Platino Company, there is a balance available of £37,559. 9s., out of which the Directors recommend the shareholders to declare a dividend of 2½ per cent. for the half-year or at the rate of 5 per cent. per annum, carrying forward £1,045. 6s. 6d. to the current account. The Directors thought that, looking at the more normal state of things in Brazil, they might make this recommendation. The improvement is not quite so finally established as we should like to see, for there is still talk of battles in Rio Grande, but looking at the existing substantial improvement, and the probability that the Government will succeed in restoring tranquillity to the country, and that there will be a consequent return of confidence and an increased development of commercial transactions, we thought we might recommend you to declare this dividend. I have now dealt with the accounts side of the question, and I have now to go to paragraph 6 in our report. If you will allow me, I will read the observations I have to make upon this matter, because I have to refer to quotations from documents, and one's memory cannot be trusted in matters of that sort. The shareholders will no doubt have seen the paragraphs in the Directors' report referring to the agreement arrived at for the payment of £6,000 per annum by the Brazilian Company to this Company in consideration of the loop lines and the contention raised by the Brazilian Company to have sole control of the rates (I will call the Brazilian Submarine Company the Brazilian Company and our Company the Western Company for the sake of clearness). The first announcement respecting this agreement was made by the late Sir James Anderson at the meeting of the shareholders of the Brazilian Company held on May 4, 1892. Sir James fully explained the advantages gained by his Company in consideration of this payment, and from the official report of that meeting circulated by the Brazilian Company I will quote word for word the statement of Sir James Anderson, as follows:—"There is one other matter I should like to refer to. You are aware that the cables of the Western and Brazilian Company are partly duplicated, and that it required the laying of a second cable between Santos and Chuy to provide a complete duplicate system between Great Britain and Buenos Ayres. The want of this complete duplication prevented the service with the River Plate being entirely satisfactory to your Directors as a strong competing line, and as it is at Buenos Ayres that the Central and South American Company can best compete for traffic, we have arranged with the Western and Brazilian Company that they shall lay the necessary cable. The cable is now being laid, and will, I believe, be landed to-day, and I am sure, this cable will lead to results greatly to our mutual advantage and success in dealing with our competitors. The cost incurred by the Western Company has been very large, and, as the Brazilian Company's fair contribution, your Directors have agreed to pay that company a fixed sum of £6,000 per annum instead of making any alteration in the percentage of the joint purse. In addition to the advantage of the extra cable, the Western Company gave us the right to use their repairing ship for repairs of our cable off the coast of Brazil at a moderate charge per day. In certain cases this arrangement will save the expense of fitting out a steamer in Europe with a long journey to Brazil and back." Now, it will be observed that not one word appears here of the contention subsequently raised by the Brazilian Company—an omission of a positively extraordinary character had such an important matter been one of the conditions as now claimed. At the Western Company's meeting, held on May 12, 1892, I, of course, made no reference to any such condition, because we did not believe any such condition existed. At this stage we were pressed by Sir James Anderson to get on with laying the loop lines, and as this was held to be of great consequence, seeing that the new opposition line was becoming a certainty, we consented to urge the work forward, relying upon the letters exchanged between the companies, and without waiting for the preparation and execution of a formal contract. The line was, in fact, completed on June 8, 1892. We were continually pressing the Brazilian Company for the draft of the agreement putting these arrangements into formal shape, which the solicitors of the Brazilian Company had to prepare, but it was not until May 12, 1892, that this was received, when the work was practically completed. The draft for the first time formally put forward this claim, and we at once objected to the clause and returned the draft for correction, and the point has been under discussion ever since. Now, the Brazilian Company appears to base its claim upon a letter addressed to us on November 23, 1891, as follows: "My Company's offer was made on the understanding that your Company would concur in any reduction which we might find to be necessary to meet competition." Now, it seems perfectly obvious that had the Brazilian Company at this time the idea to get full control of the tariff as a condition of the agreement, the Company would have said in a straightforward way: "My Company's offer was made on the understanding that your Company would concur in any reduction which my Company might find to be necessary to meet competition." But you see the Brazilian Company departs from what would have been the obvious language that should necessarily have been used to support their present claim, and instead, quits the singular altogether, and uses the plural "we"—"which we might find to be necessary"—that is, the two Companies, as we read it. Then they go on: "And that the agreement of the £6,000 per annum, &c., would be for the period of the joint purse." And again: "These points are, of course, understood between us." Now, the only understanding on our part is contained in our letter to the Brazilian Company of November 25, 1891. There was absolutely as respects this question no other, and in this letter the Western Company says: "In reference to your letter of the 23rd inst., I am directed to refer you to our letter of October 9th, wherein the question of reduction of tariffs is treated. When from competition or otherwise it is considered advisable to reduce the rates, we shall be quite willing to act in concert with you in the matter." But, now, what does the letter of October 9, 1891, say? That letter was as follows:—"My Directors would be prepared to concur in reductions of rate found to be necessary, and, as far as they can, to meet competition, and in such other

Digitized by Google

measures as might be mutually deemed advisable for the same purpose." I think that is pretty plain enough. No answer was received to the above letter of November 25, 1891, referring to that of October 9, 1891. Then, on account of the large outlay of capital and additional expenses we should be put to, we had asked the Brazilian Company on November 24th, to increase the £6,000 to £7,500 per annum, and on December 2, 1891, the Brazilian Company writes:—"I am instructed by my Directors to acknowledge your letter of the 24th ult., and to state that they are unable to go beyond the terms and amount offered you by their letters of November 18 and 23, 1891, viz., £6,000 per annum." The Brazilian Company subsequently raises the contention—at least, we suppose it does—that notwithstanding our letters of October 9th and November 25th, when that Company used the word "we," the word must be read, not in its natural plural signification as applying to both companies, as we read it, but as applying to the Brazilian Company only. But this extraordinary claim does not rest even here, for in consequence of conversations held between me and our Managing Director and Sir James Anderson, an arrangement was negotiated subsequently, under which the Brazilian Company, in consideration of obtaining the control of the tariff to meet competition, was to guarantee the Western Company's expenses, debenture interest, and debenture redemption, and the Brazilian Company's solicitors sent us on November 17, 1892, a draft of an agreement purporting to embody this arrangement. This draft, however, did not carry out properly the *pourparlers* we had with Sir J. Anderson, and, consequently, the Western Company did not see its way to proceed further. But the draft proposal of the Brazilian Company, if that Company held that it already possessed sole control of the tariff, was surely unnecessary, because under it the Brazilian Company proposed to undertake very large liabilities in order to obtain what that same Company said it had already got nearly twelve months before. The present position of this matter, however, is that late in the day on April 10, 1894, the Brazilian Company gave us formal notice of a resolution passed by their Board on April 4th that the Brazilian Company would reduce the tariff whether we agreed or not. To protect the interests of our shareholders, we were compelled to give notice of application for an injunction to prevent this, and when the day of hearing arrived, the Brazilian Company agreed without prejudice that it would not make the reduction, but failing agreement with this Company would proceed to arbitration, as provided by the joint purse agreement, the claim being referred to the Court for adjudication. The case we are advised will probably be settled before the next meeting of the shareholders, and acting under the advice of eminent counsel, we have dealt with the £6,000 per annum as detailed in the report. Meantime, the Companies have concurred in arriving at an agreement for a reduction to meet as far as may be held necessary the reductions made by the competing line, and how much further these reductions may be considered necessary will depend upon the traffic results, which are being carefully watched both by the Brazilian Company and ourselves. That ends that question. Owing to the state of the market for shipping, we have not as yet succeeded in disposing of either of the ships laid up, but we are constantly on the look out either for sale or charter in order to make the best we can of the position. Meanwhile we shall keep them in a fit state, either ready to go to sea at any moment at as small an expense as possible. The expenses will not, it is believed, exceed £800 a year. When I last reported upon the debenture reorganisation question, I said that we had surmounted all the legal impediments; but that the condition of Brazilian affairs precluded any attempt to carry out any scheme at that time. The present improved prospect of tranquillity in Brazil leads us to hope that presently we shall find ourselves at all events within more measurable distance than we have been for some time of carrying out that measure. I do not like to speak too definitely, however. We shall push the matter on as soon as circumstances are sufficiently favourable. I do not think there is anything else I need trouble you with. I have endeavoured to place the matter before you as plainly as I can, and to explain how we stand, but before putting the resolution to the meeting I ought, perhaps, to say a word with respect to the enforced absence of our Managing Director. I am sorry to say that he has had a nasty attack of the prevailing demon, and that it has been complicated by a certain amount of blood poisoning. He is at present in a very weak state, and is quite unable, of course, to be here to-day. The doctors have recommended him to go away for some time and not to think of business in any shape or way whatever. I now beg to move—

"That the report and accounts to December 31, 1893, be and are hereby approved and adopted, and that a distribution of 7s. 6d. per share (free of income-tax), being a dividend of 2½ per cent. for the year 1893, be and is hereby declared payable on the 18th inst."

Mr. C. W. EARLE seconded the motion.

Mr. ENNIS said he gathered from what the Chairman had said that the agreement referred to in the sixth paragraph of the Directors' report had not been concluded, but that both Companies were loyally adhering to the agreement as far as they could.

The CHAIRMAN: I think I had better dispose of that at once. The agreement, of course, exists in the form of correspondence as submitted to counsel. The draft, as it came on to us, contained the objectionable clause, which, of course, we could not in your interests accept. What interpretation the Brazilian Company may put upon their obligations it is impossible for me to say. We believe that we, at all events, have been loyally carrying out the agreement. We have spent about £100,000 and have duplexed our lines, and gone to very great expense for staff and appliances of all kinds. The solicitor reminds me that we were advised by Sir Horace (now Lord Justice) Davey and by others that we have a contract which is legally binding and, therefore, enforceable. In reply to another shareholder the CHAIRMAN added: the question whether the Brazilian Company under the correspondence between the Companies has the power to regulate the tariff without consulting the Western Company is the point before the Court.

Mr. FRY said that he had proposed to raise one or two questions at the meeting, but after the clear and precise explanations they had had from the Chairman with respect to the agreement with the Brazilian Submarine Company he would not do so.

The retiring Directors (Lord Richard H. Browne and Mr. C. W. Earle) were re-elected.

The retiring auditors were afterwards re-elected, and a vote of thanks to the Chairman brought the meeting to a close.

African Transcontinental Telegraph Company (Limited).

The second ordinary general meeting of this Company was held at the office, 19, St. Swithin's-lane, E.C., yesterday, the Duke of Abercorn, K.G., presiding.

The SECRETARY (Mr. Herbert Canning) read the notice convening the meeting, the report of the Directors and statement of accounts being taken as read.

The CHAIRMAN then said: Gentlemen, in submitting the usual resolution asking you to approve the report and accounts already before you, it is unnecessary for me to detain you more than a very few minutes. The report explains fully the position of the undertaking, which you will observe is divided into two sections, the southern section dealing with the portion of the telegraph from Salisbury upward towards the Zambesi, and the other, the northern section, dealing with that portion of the line running from Zomba downward to the Zambesi, including the construction of the line across that river to connect with the first-mentioned section. As regards the northern section, I desire to correct an error in our report. We refer to a portion of the telegraph route having been through a dense forest; this should have been stated as in the section south and not north of the Zambesi. I am glad to be able to add that the construction of the southern section is also substantially better than appears from the report. We learn from our mail received last Saturday that the surveyors and contractors for the Salisbury-Tete section have completed their survey, and that the telegraph way is cut for 220 miles, which is practically the whole distance between Salisbury and Tete. The work of cutting this road was very difficult, in consequence of the great scarcity of water, and the country was found to be very rocky at about 70 miles from Tete. The contractors state that they would be ready with their party to start construction at once if the material were at hand. The delay in its arrival at the western terminus of the Beira Railway (near Chimoio) is, we hope, now overcome, and the material in course of transit to Salisbury. The contractor has himself gone down to Chimoio to hasten transport matters there, and his colleague is in the meantime with a large staff of natives, digging holes for the telegraph posts, and preparing the way generally. Owing to the difficult nature of the country, we are informed that the material will, for the greater part of the distance have to be transported by native carriers. We rely upon the support of Her Majesty's Government to overcome the difficulty raised by the Portuguese as to the construction of the line within the sphere of influence of that country, and we learn that negotiations are now on foot between the two Governments to this end. I beg to move

"That the report and accounts be approved and adopted."

Mr. J. WERNHER seconded the motion, which was carried unanimously.

Mr. Robert Maguire, M.P., and Mr. J. Wernher, the retiring Directors, were re-elected, as were also the auditors, Messrs. Cooper Brothers and Co., and a vote of thanks having been passed to the Chairman and the Board, the proceedings ended.

NEW COMPANIES. STATUTORY RETURNS, &c.

ELECTRIC MOTIVE POWER COMPANY (LIMITED).—This Company was registered on May 10th, with a capital of £20,000, in £1 shares, to acquire the business, patents, rights, and assets comprised in an agreement made between Ernest J. Clubbe and Alfred W. Southey and the Company, as omnibus and carriage proprietors and carriers of passengers and goods, and electricians, electrical engineers and mechanicians, manufacturers and owners of electrical vehicles and carriages, and workers and dealers in electricity, electric machines, appliances, apparatus, motive power, heat, and light. The subscribers are:—

The first Directors are to be appointed by the signatories to the Memorandum of Association.

METALLIC DRAWING ROLL COMPANY (LIMITED).—This Company was registered on May 3rd, with a capital of £30,000 in £10 shares, to acquire certain patents, particulars of which do not transpire, and to carry on the business of ironmasters, steel makers, mechanical engineers, electrical engineers, tool makers, &c., at Manchester and elsewhere.

WILKES CONTRACT COMPANY (LIMITED).—This Company was registered on May 11th, with a capital of £5,000, in £1 shares, to contract for and maintain railways, tramways, harbours, telegraphs, and works for the use or application of electricity for light or power.

WRIGLEY'S PATENTS (LIMITED).—This Company has been registered with a capital of £60,000, in £1 shares, to acquire certain patents granted to Thomas Wrigley, and to carry on business as ironfounders, mechanical and electrical engineers, tool makers, brassfounders, metal workers, &c.

L. ALWYN (LIMITED).—The first annual return of this Company made up to February 19th was recently filed. The nominal capital is £2,000, in £1 shares, of which 1,514 have been taken up. Of these 500 were issued, with 15s. per share considered as paid, and on the remaining 1,014 shares a call of 17s. 6d. per share has been made, resulting in the payment of £891. 5s.

EDISON-BELL PHONOGRAPH CORPORATION (LIMITED).—The first annual return of this Company, made up to April 3rd, has been filed. The whole capital of £60,000, in shares of £5 each, has been taken up and allotted, and of these 4,000 were issued as fully paid.

EDISON-GOWER-BELL TELEPHONE COMPANY OF EUROPE (LIMITED).—The annual return of this Company, made up to April 12th, states that out of a nominal capital of £500,000 in shares of £1 each, 385,009 shares have been taken up, and of these 370,000 have been issued as fully paid. On the remaining 15,009 shares the full amount has been called. The Consolidated Telephone Construction and Maintenance Company (Limited) hold 209,994 shares, George E. Gouraud 94,996 shares, and Messrs. Paskas, Bailey and Gouraud 72,000 shares.

ELECTRIC AND AUTOMATIC ENGINEERING COMPANY (LIMITED).—The first annual return of this Company, made up to March 2nd, has been filed. Out of a nominal capital of £10,000, in shares of £1 each, 47 shares have been taken up, and upon each of these the full amount has been called. The Assets and Debenture Securities Corporation (Limited) hold the 40 shares.

ELECTRIC EXPLOITATION COMPANY (LIMITED).—This Company has just entered into an agreement with Max Sussmann, of Neuruppin, in the Kingdom of Prussia, which provides for the sale to the Company of Letters Patent and Provisional Specifications granted to him for "a portable secondary battery lamp for use in mines and other places, for "improvements in the manufacture of secondary battery plates," and for "improvements in or connected with so-called 'dry' electrolyte for secondary batteries," and all his interest in the same. The purchase consideration has been fixed at £20,000, payable by the allotment as fully paid of 20,000 shares of £1 each, Nos. 8 to 20,007 inclusive. Inasmuch as certain gentlemen have assisted the vendor by the advance of money, and by introducing the inventions, he has stated that the following shares will be transferred to them :—John Aldwinckle (4,562), Sigmund A. Rosenthal (4,375), Robert Lawson (250), William Lawson (250), Villeroy C. Doubleday (750), John A. Buchanan (688), Archibald Gray (250), Hugh O. Macan (125), William Wood (750), Percy C. Atkins (375), George Watson (63), and Alaric H. Tredwen (62).

FAREHAM ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to April 4th, was recently filed. Out of a nominal capital of £5,000, in £1 shares, 4,154 shares have been taken up, the full amount called, and all calls paid.

FOREIGN PILSEN ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company made up to March 15th was recently filed, when 29,800 shares out of a nominal capital of £30,000, in £1 shares, were taken up, and all issued as fully paid to the shareholders in the Union Electric Light and Power Company (Limited).

HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to April 5th, has been filed. The nominal capital is £350,000, divided into 57,900 Ordinary, 100 Founders', and 12,000 Preference shares of £5 each. 8,322 Ordinary, 100 Founders', and 5,000 Preference shares have been taken up, and of these 100 Founders' and 1,000 Ordinary were issued as fully paid. Upon the remaining 7,322 Ordinary and 5,000 Preference shares the full amount has been called, resulting in the total payment of £61,610.

INDIA-RUBBER, GUTTA-PERCHA AND TELEGRAPH WORKS COMPANY (LIMITED).—The annual return of this Company, made up to March 1st, has been filed. Out of a nominal capital of £812,000, in £10 shares, 50,000 have been taken up, the full amount called, and all calls paid.

KESWICK ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to March 9th, was recently filed. Out of a nominal capital of £5,000, in £1 shares, 3,420 have been taken up, the full amount called, and all calls paid.

LANCASHIRE AND CHESHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The annual return of this Company, made up to January 11th, was filed on May 9th. Out of a nominal capital of £100,000, divided into 19,900 Ordinary and 100 Founders' shares of £5 each, 100 Founders' and 7 Ordinary shares have been taken up. The Founders' shares have been issued as fully paid to the House-to-House Electric Light Supply Company (Limited), of Richmond-road, Earls Court, London, S.W., and no calls have as yet been made upon the seven signatories' shares. Similar returns have been filed by the Liverpool, the Manchester, and the Northern House-to-House Electricity Companies (Limited).

LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to March 9th, was recently filed. The nominal capital is £300,000, in £5 shares, of which 45,000 have been subscribed for and allotted. On each of these shares the full amount has been called, resulting in the payment of £220,985. 10s., and leaving £4,014. 10s. in arrears.

MEXICAN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this concern, to November 28th last, has just been filed. The whole nominal capital of £100,000, in shares of £20 each, was considered as fully paid. Messrs. Gibbs and Gibbs, of 15, Bishopsgate-street Within, London, E.C., hold 4,993 of the shares.

NORTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to March 8th, has been filed. Out of a nominal capital of £50,000, divided into 10 "A" and 49,990 "B" shares of £1 each, 10 "A," 10,000 "B" Ordinary, and 3,200 "B" Preference shares have been taken up. No calls have been made on the "A" shares, while the full amount has been called on the other class, resulting in the payment of £13,200.

NORTHERN ELECTRIC WIRE AND CABLE MANUFACTURING COMPANY (LIMITED).—The annual return of this Company, made up to April 25th, has been filed. The capital of £20,000 is divided into 660 fully-paid and 3,340 Ordinary shares of £5 each. All the former and 2,267 of the latter class have been taken up, and a call of £2. 10s. per share has been made on the Ordinary shares, resulting in the payment of £5,665, and leaving £2. 10s. in arrear.

CITY NOTES.

CHAGFORD AND DEVON ELECTRIC LIGHT COMPANY (LIMITED).—A meeting of this Company was held on Friday, at which the Directors' report and the accounts and the Manager's report were adopted by the shareholders. The manager (Mr. G. H. Reed) reported that fresh applications for additional lights were constantly being received, and that the lights continued to give entire satisfaction. The Company was making satisfactory progress, and was expected shortly to be in a position to pay a satisfactory dividend. Mr. Reeves, a Director, stated that he had examined the works thoroughly, and as a practical electrician, had pleasure in reporting that the works had been carried out and the cables laid in a manner highly creditable to Mr. Reed, and that the whole was now in a satisfactory condition.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended May 13th were £905, as against £787 in the corresponding period of 1893, being an increase of £118. The total receipts for the half-year amount to £17,305, as against £16,941 for the corresponding period of 1893, an increase of £364.

HOTEL LIGHTING.—An adjourned general meeting of the Brighton Grand Hotel Company (Limited) was held yesterday at the Cannon-street Hotel, under the presidency of Mr. B. H. Van Tromp, to receive the joint report of the Committee of Conference and the Board of Directors appointed last February to report on various economies and in regard to the electric light. The report, after dealing with the circumstances under which the electric light installation was put down, said that, although an error of judgment had been committed, the Directors did at the time what seemed wise under the circumstances. There was no doubt that the cost of the electric light during the past two years had been excessively high. The Board had, however, under professional advice, during the past year been making efforts to bring about a reduction, which the Directors thought might be reasonably estimated at from £500 to £600 per annum. The Brighton Corporation had, however, submitted an estimate for lighting the hotel, which promised even better results, and it had been arranged that a supply of electricity from the Corporation shall be first made for one year, in preference to continuing the use of their own installation, even under the improved conditions referred to.—Mr. J. Broad went into figures as to the cost of the coal used for the electric light in the years 1891, 1892 and 1893, and he maintained that the proportion used by the Hotel Company was larger than that used by the Brighton Corporation. He stated that, at the request of the Committee, they obtained the services of Mr. Wright, who was the manager of the electric light works for the Brighton Corporation, who found that there were 675 lights of 8-c.p., 32 of 10-c.p., 109 of 16-c.p., and seven of 25-c.p. They reduced all these to 8 c.p., making a total of 952. Mr. Grunholt said that his experience of the electric light at Richmond was that for his hotel it cost him some 50 per cent. more than he paid for gas; but the difference in the light—its brilliancy—was 200 per cent. more in worth, and therefore he was quite willing to pay the difference as between electric light and gas. The Directors' report was adopted.

PANULCILLO COPPER COMPANY (LIMITED).—At an extraordinary general meeting of this Company, held on Wednesday, the resolutions passed at the meeting held on the 24th ult., authorising the transfer of the undertaking to a new Company, were confirmed.

Digitized by Google

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY (LIMITED).—Mr. D. R. Plunket, Q.C., M.P., and Mr. Anthony Noel Denny, have been appointed Directors of this Company, Mr. Plunket becoming Chairman of the Board.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended May 11th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,891.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 836.—Vol. XXXIII. FRIDAY, MAY 25, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/*

NOTES.

An article by Dr. John Hopkinson, which appears in another column, gives a simple and interesting discussion of the formula for the force exerted by an electromagnet upon its armature. Quite apart from the importance of the subject itself, this article has special interest for us from two points of view. In the first place, it is an example of the use of graphic constructions, which we recently taxed Dr. Hopkinson with undervaluing in his Forrest Lecture on the applications of mathematics to engineering. In the second place, it introduces the term "characteristic" as a synonym for curve of magnetic induction, as distinguished from its original use to denote the curve which in a dynamo or motor gives the relation between amperes and volts.

We give in the current number a first instalment of a Paper by Prof. Galileo Ferraris, which will be of great value to all those who are interested in the problem of the alternate-current motor. It relates to a method of treating by graphic calculation or by simple trigonometric symbols the quantities with which the electrician has to deal in considering rotatory magnetic fields and the so-called rotatory current. It has been evident for some time that a new and simple calculus was desirable for handling such problems, and this has now been provided by Prof. Ferraris, who has thus doubled his claims on the scientific world in this department of modern electrical work. We venture to think that our readers will prefer the simplicity of the new method to the more cumbrous calculations employed by Sahulka, Arnold, and others. It is one of the many curious coincidences in science that an almost identical method was independently worked out in France and published only a few days later than the memoir of Prof. Ferraris. The translation (from the original Italian) is from the pen of a lady whose face has been occasionally seen at the meetings of the Institution of Electrical Engineers.

The proper use of glow lamps for domestic purposes is gradually becoming understood, but there are, unfortunately, many examples of lighting which fully deserve to be called "bad for the eyes" or "unbecoming." The very liberty with which the lamps may be used affords opportunity for inartistic brass work and unintelligent arrangement. But in the hands of a decorative artist the possibilities of domestic electric lighting are as delightful as they are inexhaustible. Domestic lighting need only please, as a rule, two persons, and of these two one is of minor importance, for he has only to pay for it; but the lighting of public buildings is a more responsible matter. To please a sub-committee is possible, to satisfy the authorities is difficult, but to please the general public is practically out of the question. No wonder then that there seems to be some difference of opinion about the success of the experimental lighting of St. Paul's Cathedral. The ugliness of the wood and paper contrivances which have been stuck here and there on the piers cannot be denied, even when allowance has been made for the temporary character of the work. Gen. Webber has defended this experimental work, for which he assumes the responsibility, and gives three objects of the tests, namely, to compare arc and glow lamps, to give sufficient light, and to avoid glare. We hope that some competent person is fully alive to a much more important object than any of these, and that is to ensure a strict observance of the canons of architectural decoration. Whether St. Paul's be lighted by electricity or no is of small importance, provided that in the lighting the edifice be not defaced, and we say this with less hesitation since we are confident that it can well be done. Arc lamps bearing the makers' names on the globes have been used in a church in this country, but that would displease an ordinary vestryman; the evils to be avoided in this case are those which would offend cultivated architects and connoisseurs.

From some remarks of Prof. Kennedy at the last annual dinner of the students of the Institution of Civil Engineers, we are given to understand that the poor attendance at Students' Meetings is "engaging the serious attention of the Council," and that there is some idea of excluding students from the joys of associateship until they shall have put in an appearance at 250 meetings at least. The most obvious way to secure a good attendance would seem to be to exhaust every effort to secure good Papers, and judging by the quality of the Papers that are occasionally printed in the *Proceedings* of the Institution of Civil Engineers, this device would appear to have been tried. Perhaps a little more publicity is what is wanted, and in the case of the Students of the Institution of Electrical Engineers we have endeavoured as far as we can to give it. An even better minimum than the one suggested would be a receipt for at least 250 pence spent on technical journals.

When electrical engineers have discussed sufficiently exhaustively the relative values of Welsh coal and bituminous

Digitized by Google

slack, and the comparative merits of Lancashire and water-tube boilers, there is another question, which quite as much affects the economy in electric supply stations, which they will have to face. We refer to the problem of how far it is economical to try to economise. The number of appliances for "saving half the coal," which are offered on every hand to electrical engineers, are almost countless; there are furnace economisers, exhaust steam economisers, "hydrogen units" economisers, oil economisers, &c., &c. But the question which will some day have to be answered is, How far does it pay to practice all these economies? This is a problem from which the mathematician must be bowed out, his formulæ and his assumptions are unavailing. Practical experience alone can justify or condemn the expenditure of any given amount of capital on any given proposed economy.

We are a long way from having arrived at a satisfactory solution of this problem, but experience already acquired justifies the engineer in believing that an approximate estimate may in some cases be made. All would be comparatively plain sailing if our electric supply stations worked at 100 per cent. load factor. But it is the remembrance that for a great proportion of the time his adopted economisers will be lying quite or partially idle, while all the time there is the item "interest on capital expended" eating its way into the annual balance-sheet, which makes the electrical engineer hesitate to decide just how large an economy he ought to arrange for. He knows well enough that that is the best plant which is designed according to a sort of Thomson's law, but the Sphinx's riddle is, what size of plant *will* be according to that law?

Our esteemed contemporary, the *Engineer*, has lately directed its attention to the important question of the best arrangement of generating stations for Metropolitan electric supply. It arrives at the conclusion that a large number of detached generating stations, such as now exists, is the least likely method to yield a profitable return for the capital invested, and it bases this conclusion upon a very plausible line of argument. "No one in his senses," it says, "fancies that a gas works could be constructed near Berkeley-square to supply 60,000 lights which would prove remunerative. Why should an electric light station?" Why, indeed, except that the cases, whilst having something in common, are by no means on all fours. The coal cartage nuisance in the case of electric lighting stations, is, as Mr. Kapp points out, an almost negligible quantity, but in the case of a gas works it would be a formidable problem. The only way in which an electric lighting station usually offends its neighbours is by setting their dwellings on the wobble; its area of nuisance is concentrated. A gasworks, on the contrary, has an almost indefinite area of nuisance. A Paper was recently read before a scientific society on the audibility of Big Ben at Norwood and its connection with the weather. We could wish that its author would investigate in like manner the influence of meteorological conditions on the limits of "smellibility" of a gas works.

Our contemporary thinks that existing stations should be turned into sub-stations, and that they all should be fed from one and the same generating station, situated at some place outside the metropolitan area, a "peripheral station" as Mr. Kapp calls it. The existing companies might even purchase their supply of electrical energy from the owners of this fountain head, and retail it to their own little coterie of consumers. The main point, though not the only one, upon which our contemporary bases this system of electric power distribution, is the fact that by supplying power to the entire metropolitan area from a single station, a much better load factor could be obtained, than where the area is subdivided into detached and independent districts. One portion of the area would find work for the station in the daytime, another portion in the early evening, and a third portion in the midnight hours.

To properly light the metropolis, 8,000,000 lamps of 8-c.p., or their equivalent, would be necessary; and our contemporary estimates that a provision of 200,000 H.P., would be required, in order to meet this demand. This figure is based on the assumption that the maximum load on the station is equal to half the lamps wired. In this assumption we cannot concur; for we consider that, in any such comprehensive station as the one proposed, the maximum number of lamps in use at any one time would be very much below one half of the total lamps wired. Our contemporary forgets that the very principle upon which it proposes to improve the load factor of the station, must directly operate to reduce the ratio of the maximum lamps *used* to the lamps *wired*. If the commingling of diverse districts is to considerably improve the one quantity, it must of necessity reduce the other; because it can only operate if different districts, or classes of consumers, are in full action at different times. Now, it is very rarely indeed that existing detached stations experience a load equal to 50 per cent. of the total lamps connected. Therefore, it is highly probable that, by the coalescence of several stations, this figure would be considerably lowered.

The fundamental principle of patents for inventions, in this and in other countries where it has been imitated, is that of a bargain made between the State and the inventor. Protection for a limited period is granted on condition that the invention shall be freely thrown open or made patent to the public on the expiry of that period by a full description of the details; and, in order that the public may know what matters are under State protection, this full description is published as soon as possible after the protection has been granted. A list of the names and numbers of patents which have expired or have been dropped is issued by the Patent Office, but probably receives little attention; the public have to find out, as best they may, whether the bargain is at an end. We have from time to time called attention to patents for well-known inventions, as the term of fourteen years has expired, and amongst these it may be noted that the Maxim dynamo and Pilsen arc lamp thus ran out last month. The United States Patent Office appends to its *Official Gazette* a list of patents whose term of seventeen has expired. The list is illustrated, and the inventions are easily recognised. The majority of expiring patents in the last *Gazette* are dated

Digitized by Google

May, 1877, and contain but a single electrical item, PRESCOTT'S quadruplex telegraph. A British list would be more interesting, on account of the more modern character of the inventions, owing to lapse by non-payment of annuities.

Royal Society.—The Ladies' Conversazione is announced for Wednesday, June 13th.

Wolverhampton.—On Monday afternoon the Mayor of Wolverhampton (Alderman C. T. Mander) laid the foundation-stone of the Municipal Electric-lighting Works.

Personal.—Herr F. Uppenborn, editor of the *Elektrotechnische Zeitschrift*, has been offered and has accepted the appointment of municipal electro-technical engineer to the city of Munich.

The Sir John Pender Gold Medal.—At the recent distribution of prizes in the Glasgow and West of Scotland Technical College, Mr. J. Fred. Nielson was awarded this medal for excellence in electrical engineering.

The Leipzig Electrical Exhibition.—The *Elektrotechnische Zeitschrift* announces that, in spite of the short duration of the forthcoming (June 8th-17th) Electrical Exhibition at Leipzig and the general indifference displayed, over one hundred firms will be represented.

Electricity and Gas.—A Glasgow evening newspaper declares that the verdict of a certain individual who has used the electric light in that town is: "Cost four times gas, and saved a dozen boxes of matches in a year." We may be sure, at any rate, that he saved the matches; the other calculation may have dropped a coefficient somewhere.

Long-Distance Telephony in India.—Following upon the experiment of telephoning from Calcutta to Nagpur, an attempt was made the other day, says *The Englishman*, to communicate directly with Bombay, a distance of 1,500 miles. The results were not very satisfactory. The telephone line between Chicago and New York covers a distance of about 1,000 miles.

Electric Supply in America.—President E. A. Armstrong, in his address before the National Electric Light Association, said that according to the most trustworthy information available there were now in the United States upwards of 2,300 electric supply undertakings, representing an invested capital of £40,000,000; and it was estimated that at least an equal amount was invested in the manufacture of electrical machinery and supplies.

Portsmouth.—While making a trial run, a few days ago, the armature of the Parsons 150 kilowatt steam turbine-alternator was burned out, necessitating its removal to Newcastle for repairs. The burn out is all the more remarkable, as it is said that the armature was on open circuit at the time. It is expected that the accident will not interfere with the success of the inaugural ceremony at the station, which is fixed for Wednesday, June 6th.

Aberdeen.—The electric light station has been thrown open to the public on Saturday afternoons between the hours of four and six. Last Saturday about thirty persons—mostly mechanics—availed themselves of this opportunity of visiting and inspecting the plant. The assistant-engineer was in charge, and conducted the visitors over the different parts of the station. About a score of people visited the gasworks, and were shown over the whole process of manufacture from beginning to end.

Royal Society.—The following were some of the Papers down for reading yesterday before the Royal Society:—Messrs. J. W. Swan and J. Rhodin, "Measurements of the Absolute Specific Resistance of Pure Electrolytic Copper;" Mr. J. W. Swan, "On some Voltaic Combinations with a Fused Electrolyte and a Gaseous Depolariser;" Prof. T. Gray, "On the Measurement of the Magnetic Properties of Iron;" Prof. Threlfall and Messrs. J. H. D. Brearley and J. B. Allen, "Researches on the Electrical Properties of Pure Substances. No. 1.—"The Electrical Properties of Pure Sulphur."

Forewarning by Telegram.—Some months ago a serious landslip occurred at Gohna, in the Gurhwal district of Bengal, blocking the flow of a considerable river and converting a valley into a huge lake. Since then the water has been gradually rising, and it is feared that when it overtops the dam it will carry it away, notwithstanding the enormous thickness of the latter, and cause a most destructive flood. The *Times* Calcutta correspondent says a temporary telegraph line is now being constructed from Hurdwar to the spot in order to give timely warning to the people inhabiting the threatened tracts; but apparently no measures are being taken to try and avert what may be a terrible disaster. The water is still 200ft. below the top of the dam, but it may now be expected to rise rapidly, as the snow will soon melt with the advance of the season.

Ealing.—A long discussion took place at the meeting of the Ealing Local Board on Thursday last week, concerning the position in which the electric lamps shall be placed in the Uxbridge-road from the Broadway to the boundary of the district at Hanwell. There were three propositions before the Board—one being that the lamps should be erected in the centre of the road; a second that they should be placed by the side of it; and a third that they should be erected alternately at the side and in the centre of the road. Each of these propositions was put to the vote, and lost in turn, the supporters of the second and third-mentioned plans combining together to defeat the original proposition that the lamps should be erected in the centre of the road. Having thus deadlocked themselves, the municipals left the matter for final decision to the engineers.

The Heilmann Locomotive.—In a recent number of *L'Elettricista* of April 1st, M. Brunelli points out that, although the results given by the Heilmann so-called electric locomotive have not been better than those obtained from the usual type of locomotive, it must be remembered that while the Heilmann machine is on a quite new and original principle, which is susceptible of improvement, the usual type has probably reached it highest perfection. The Heilmann locomotive may succeed ultimately, as it is only in fact a steam locomotive in which the transmission take place electrically. It must be remembered that the power supplied by the usual locomotive is much more costly than that produced by an ordinary steam-engine, and also that the present system of transmission is very detrimental to the permanent way. The Heilmann plan may in these respects prove an economical one.

Gas and Electricity in Birmingham.—At a meeting of the Birmingham City Council on Tuesday, the chairman of the Gas Committee said that three important factors had influenced the accounts of the gas department—the coal strike, the decrease in the consumption of gas, and the increase in the price. During last year the consumption of gas decreased by no less than 6 per cent., and when compared with the sale of two years ago, last year's consumption showed a decrease of 26 million cubic feet. That reduction he attributed to four causes—the bright weather during the year, the bad trade, the introduction of electric light, and the greater use of economical burners. The conclusion he had arrived at was that they would no longer see the giant strides by which the consumption of gas had risen in 18 years from 2,300 to 4,000 million feet, but that there would still be a gradual, if slow, increase.

Civil Engineer Students.—At the nineteenth annual dinner of the students of the Institution of Civil Engineers, held at the Holborn Restaurant, on the 11th inst., Prof. Kennedy, speaking of the poor attendance of students on Friday evenings, said that the matter was engaging the serious attention of the Council, and suggested that a minimum attendance of say, 250 meetings, by the student presenting himself for admission to the associate membership, should be requisite. Mr. Godfrey. student, in responding for the local associations, was understood to complain that so long as students of the Institution had to pay a fee of ten guineas in addition to passing an examination to become an associate, he thought a further condition such as that mentioned by Prof. Kennedy could be dispensed with when

Digitized by Google

it was considered that outsiders were admitted as associate members simply by election by the Council on payment of the fee. It might be further urged that most of the out-of-London students could not attend many meetings, and further that attendance at meetings gave no clue to a student's ability, much as it might give as to his serious desire to "pass."

Cardew's Vibrator.—The following letter from Major H. F. Chesney, R.E., which appeared in *Engineering* last week, will be read with interest:—

SIR,—To those of your readers who are interested in telegraphy, a short description of the successful manner in which long interrupted lines were worked through, with the aid of the Cardew's vibrating sounder, during the late severe weather in Persia may be of interest. On the first occasion all the wires were buried under mud and water in the *débris* of a village which had been destroyed by flood. For nearly 24 hours all the international traffic between Europe and the East, which is carried by the Indo-European Telegraph Company and Department, was transmitted between Ispahan and Shiraz, a distance of 332 miles, by means of Cardew's sounders, working through the above-mentioned dead earth. When it is remembered that nearly the whole of the traffic consists of difficult code and cypher messages, the importance of the result achieved can be understood. During this period the ordinary Morse instruments were, of course, useless. On the other occasions the traffic was passed between Shiraz and Bushire, a distance of 186 miles, in the same manner, and interruptions of six and eighteen hours respectively saved. I believe these instruments have not hitherto been successfully used on lines of this length, and certainly not to carry international traffic.

Lamp Shades.—The following letter, signed A. Dupré, appeared in *The Times* of Wednesday. As the material referred to is so much used to swathe up the modest 8-c.p. glow lamp, the letter will be read with interest by others than users of duplex lamps:—

SIR: If you could find room in your widely circulating paper for the following lines, they may be the means of preventing accidents similar to the one which happened at my house on May 10th. On the evening of that day one of my children complained that a smell of burnt paper was perceptible in the house. This smell had been noticed some hours previously, but was not then traced to its source. A careful search led to the discovery that a paper lamp-shade in one of the rooms had been entirely consumed by fire. For two days prior to the accident the lamp, a duplex, had not been lighted, and there had been no fire in the room. Since the morning of that day, when the room was dusted and the shade apparently in its usual condition, no one had entered the room. The shade was made about a year ago from so-called crinkled tissue paper, one white and one yellow sheet, gathered together on the upper part where it was fixed to the wire frame, where it formed a considerable bunch, and spreading thence over the frame below. On examination the yellow paper was found to be coloured by chromate of lead, and this, no doubt, was the cause of the accident. There can, I think, be no doubt that this was a genuine case of spontaneous ignition, though I have not as yet been able experimentally to reproduce the necessary conditions leading to such a result. Fortunately there were no readily inflammable articles near, or a serious fire might have resulted, the origin of which would probably never have been suspected. The dangerous paper is readily recognised by setting fire to a piece of it and blowing out the flame. In the case of ordinary paper it will be found that the glow along the burnt edge is very soon extinguished, whereas, in the case of these chromatic papers, it continues until the whole is consumed, as is the case with ordinary touch-paper. I find that besides the yellow paper, pale green paper also contains chromate of lead, and would, no doubt, be equally dangerous, and possibly there are papers of other colours containing the same material. It would be interesting to learn whether any similar case has been observed before.

American Institute of Electrical Engineers.—At the meeting of this Institute, which was held in Philadelphia on the 15th, 16th, 17th, and 18th inst., the following Papers were down for reading:—"On Light Distribution and the Use of Lamps," by Prof. Wm. A. Anthony; "Discriminating Lightning Arresters and Recent Progress in Means for Protection Against Lightning," by Alexander Jay Wurtz; "Central Station Economy," by C. Reginald Van Trump; "Unipolar Dynamos for Electric Light and Power," by Prof. Francis B. Crocker and C. Howard Parmly; "Relative Advantages of Toothed and Smooth Core Armatures," by Alton D. Adams; "Test for Closed Coil Arc Dynamo," by Prof. R. B. Owens; "Alternating Currents and Fuse Wires," by Prof. Dugald C. Jackson and R. J. Ochsner; "Some Storage Battery Phenomena," by W. W. Griscom; "The Waste of Zinc in Open Circuit Batteries when Standing Idle," by Henry A. Lardner; "Standardising Electrical Measuring Instruments (*a*) by the Potentiometer Method; (*b*) an Improved Direct Reading Potentiometer," by Elmer G. Willyoung; "Resonance Analysis of Alternating and Polyphase Currents," by Prof, M. I. Pupin; "Some Facts About Polyphase Motors," by Dr. Louis Bell; "The Law of Hysteresis (Part 3) and the Calculation of Ferric Inductances," by C. P. Steinmetz; "Experiments with Two-Phase Motors," by Dr. Louis Duncan.

The Field Electric Railway Patent.—Judge William K. Townsend, of the United States Circuit Court, at New Haven, Conn., on May 3rd, rendered an important decision on a final hearing of a bill in equity, alleging infringement on letters patent, granted to Stephen D. Field, July 16, 1889, for improvements on electric railways and assigned to the complainant, whose motion was finally denied. The evidence of infringement, as stated in the decision, applies to the combination of a stationary dynamo-electric generator driven by a suitable motor and circuit of motors, composed in part of an insulated or detached section of the line of rails of the railway track and the electric magnetic motor mounted on a wheeled vehicle and used for propelling the same, and included in a circuit of conductors; also a current-controlling device placed upon such vehicle. The defence was a denial of infringement, anticipation by prior patents, publication, and prior inventions. Judge Townsend states that the complainant admits that every element in the invention existed in art before the combination was made, and he finds that there was a question in the Patent Office in 1879, as to whether patents could be granted to Field, because of a prior patent, known as the Clark, which embodied the same principle.

Magnetisation of Iron at High Frequencies.—At a recent meeting of the Kaiserliche Akademie der Wissenschaften of Vienna, Prof. Klemencic read a Paper on the magnetisation of iron and nickel wires by rapid electrical oscillations. An abstract of this is given in *Nature*. From the amount of heat developed in a wire of a magnetic material traversed by electrical oscillations, the author calculates, by means of the formula given by Lord Rayleigh and Stefen, the value of μ (the permeability). The heat developed in the wire under observation was determined by means of a thermoelectric couple, and was compared with the heat developed in a non-magnetic wire under similar circumstances. The following are some of the values obtained for μ:—Soft iron, 118; steel wire, soft 106, hard 115; Bessemer steel, soft 77, hard 74; nickel 27. These values agree very well with those obtained by Lord Rayleigh and Bauer for very feeble magnetising forces. The results obtained by these observers show that for certain values of the magnetising force the permeability is constant, and that it afterwards rapidly increases. Now the results obtained by the author show that over the range he is employing μ has a constant value. This fact may be explained either by supposing that the magnetising forces employed are so small that we are dealing with that part of the curve where μ is constant, or that, although the magnetising forces are much greater than those to which the former supposition limits us, the magnetisation is unable to follow the rapid changes in the magnetising force, so that the magnetisation never reaches that part of the curve where μ is variable and has very much greater values. A rough estimation has shown that, at least on the surface of the wire and at the commencement of the oscillations, the magnetising force exceeds more than a hundredfold the maximum limit within which μ is constant. Thus, in these experiments there must exist a time lag in the magnetisation which must not be confused with the hysteresis. It would also appear that Bauer and Lord Rayleigh's results which refer to longitudinal magnetisation, also apply to circular magnetisation.

The Electrical Trade Section.—In the twelfth annual report presented by the Council on Monday last to the members of the London Chamber of Commerce the following paragraph is devoted to the Electrical Section:—During the year this Section and its committees have held twelve meetings. The Section has again had under its consideration the Regulations of the Board of Trade on Overhead Wires. The Board have hitherto refused to modify these regulations, on the ground that they were drafted in consultation with the Institution of Electrical Engineers, and until alterations were recommended by that body they saw no reason to depart from the attitude already taken up. It is satisfactory to record that the Institution of Electrical Engineers has now recognised that, looking to the commercial aspects of the in-

Digitized by Google

dustry, it is absolutely necessary that these regulations should be to some extent modified, and negotiations were in progress at the end of the year which it was believed would remove the disabilities from which the industry now suffers in this respect, consistently, of course, with a due regard for the public safety. Another question considered by the Section during the year was the position of the electrical industry in reference to the Telephone Company's monopoly of the use of earth. Recognising that this position was a serious hindrance to the development of the traction industry, the Section resolved upon the appointment of an Electrical Traction Committee, which should have power to raise funds, engage counsel, and take such other steps as might be, in the opinion of the Committee, necessary for the advocacy or propagation of traction interests. This Committee was in due course constituted, and presented its case before the Joint Committee of the Houses of Lords and Commons on Electrical Power, with results entirely satisfactory to the traction industry. At the close of the year the Traction Committee were in communication with the Board of Trade as to the regulations under which the industry might be carried on consistently with the recommendations in the report of the Parliamentary Joint Committee already referred to. The Section also directed its attention to the National Telephone Company's Powers Bill, railway rates on electrical goods, and the desirability of the promotion of lectures on the commercial aspects of the industry during the winter months.

Technical Literature and Style.—Commenting not long since on the speeches made at the Royal Literary Fund dinner, the *Standard* directs attention to the decay of style, and enters a protest which comes, we think, none too soon. "The time was," says our contemporary, "when no one was in any doubt as to what was literature. Those who wrote for the public were few in number; and, even where they had little or nothing to say, they took care to say it in a certain manner, and conformed to well-ascertained canons of composition. But with the assertion of individual liberty that accompanied and followed the French Revolution, the standard of taste and correctness in writing was overthrown, and by degrees everybody began to think that it was open to him to write as he pleased, without the smallest reference or regard to the great and acknowledged masters of style who had preceded him." The utilitarian views, observes the *Engineer*, which in most of the affairs of this century are for ever battling with the æsthetic are as much to the front in our technical literature as in any other direction. To the eye of the world at large the engineer is a person whose connection with poetry and delicate feeling is similar to that of Tommy Atkins with the Grand Turk—that is to say, if it exists at all it is antagonistic. If it were possible to record in the census the number of men possessed of certain poetic faculties—by which we mean an appreciation of the true and beautiful, and not an ability to string jingling words together—we are inclined to believe that amongst those professing mechanical crafts the percentage would be far above the average. We regret to feel that in a technical journal these observations seem out of place, and we hasten to give our reason for having made them. Through the hands of a reviewer there passes annually a large number of books devoted to technical interests, and it is against the utilitarian style which disfigures the greater number of these volumes that we wish to protest. It must be understood, however, that we employ the adjective "utilitarian" in its worse sense, the sense which means that man forgets his higher nature and becomes a grubber after a material building up, and an intellectual down-pulling. The disease begins in a text-book, and reaches—at present—its climax in a catechism. In the text-book form it may be so mild as to be practically harmless; in the catechism it attains astonishing virulence; and in the "telegram" stage, to which it is tending, high fever will be reached. If brevity is the soul of wit, dwarfishness is the crown of ugliness. If utility is the criterion of art, utilitarianism is the measure of ungracefulness. Are we to have the style of printed literature reduced to that of the manuscript pocket-book? Does it not seem a disgrace that we accept work after work, and whilst admiring the author's depth of knowledge, never censure his ignoble style? Surely some attempt should be made to keep our English language at a high level, and we should be prepared to sacrifice some little brevity for the sake of a little more grace.

The Royal Society Selected Candidates.—Our readers may be interested in reading the qualifications of some of the selected candidates for Fellowship of the Royal Society, which, though they may be briefly stated, represent in many cases long years of painstaking research:—HUGH LONGBOURNE CALLENDAR, Fellow of Trinity College, Cambridge, Lecturer on Physics, has made important investigations on the measurement of temperature by electrical means. These are described in the Papers, "On the Practical Measurement of Temperature" (*Phil. Trans.* R.S., 1887, A, page 161); "On the Determination of the Boiling Point of Sulphur, and on a Method of Standardising Resistance Thermometers by reference to it" (*ibid.*, 1891, A), (this Paper is written in conjunction with Mr. Griffiths); "On the Construction of Platinum Thermometers" (*Phil. Mag.*, July, 1891); "Some Experiments with a Platinum Pyrometer on the Melting Points of Gold and Silver" (*ibid.*, February, 1892).——— JOHN VIRIAMU JONES, B.Sc. (Lond.), Principal and Professor of Physics in the University College of South Wales and Monmouthshire, Fellow of University College, London. Distinguished for his acquaintance with physics. Engaged in the teaching of physics as well as in the organisation of scientific studies, and is anxious to promote the progress of science. Author of a memoir "On the Determination of the Specific Resistance of Mercury in Absolute Measure" (*Phil. Trans.*, Vol. CLXXXI.,1890). Author also of the following Papers:—"On the Calculation of the Co-efficient of Mutual Induction of a Circle and a Coaxial Helix" (*Proc.* Phys. Soc., Vol. X.); "On the Use of Lissajous' Figures to determine a Rate of Rotation, and of a Morse Receiver to measure the Period Time of a Reed or Tuning-fork" (*ibid.*); "Suggestions towards a Determination of the Ohm." Read before the British Association at Leeds, 1890 (*The Electrician*, Vol. XXV.).———Rev. FREDERICK JOHN SMITH, Clergyman of the Church of England, Millard Lecturer in Experimental Mechanics, Trinity College, Oxford. Distinguished for his researches in practical mechanics and physics, and the invention of important dynamometric and integrating instruments; also of the chronograph—registering graphically periods of time from ·00005 sec. to 1·0 sec.—now used in the measurement of the flight of projectiles and in physiological research. Author of numerous Papers, among which may be mentioned:—"An Experimental Investigation of the circumstances under which a Change of the Velocity in the Propagation of the Ignition of an Explosive Gaseous Mixture takes place in Closed and Open Vessels. Part I.—"Chronographic Measurements" (*Proc.* Roy. Soc., Vol. XLV., 1889); "Description of Dynamometer and Integrator for Measuring the work done in Driving Dynamos and other Machines" (*The Electrician*, 1881); "Ergometer or Work-measuring Machine" (*Phil. Mag.*, Vol. XV., 1883, and *Nature*, Vol. XXX.); "A New Form of Electric Chronograph" (*Phil. Mag.*, Vol. XXIX., 1890); "On Some New Methods of Investigating the Points of Recalescence in Steel and Iron" (*ibid.*, Vol. XXXI., 1891); "On Some of the Effects of Magnetism on Rods of Iron, Nickel, and other Metals which have Received a Permanent Torsional Set" (*ibid.*, Vol. XXXII, 1891).———JOSEPH WILSON SWAN, M.A. (*honoris causa*) Durham, F.C.S., F.I.C. Has devoted himself for many years with great success to experimental scientific work, chiefly in relation to electric lighting, the electro-deposition of metals, and the improvement of Photographic processes. His labours have resulted in material extension of knowledge, and in important inventions, among which are the incandescent electric lamp, the carbon process, by which the first permanent photographic prints were produced and which has formed the basis of many processes of photo-mechanical engraving (in this relation the property of salts of sesquioxide of chromium to combine with gelantine and render it insoluble was discovered), the highly sensitive gelatino-bromide photographic plate, the result of an original observation of the effect of heat on the gelatino-bromide of silver emulsion, the cellular form of electrical secondary battery plate, the production of lamp filaments from solutions, integrating electric meters, safety lamp for miners, and an electric firedamp indicator.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 73.*)

Furnaces and Boilers.

Furnace Temperature.—In a completely enclosed furnace, *i.e.*, one surrounded entirely by non-conducting walls, the furnace temperature may be calculated from the weight of coal and air involved in the production of a given amount of heat. Practically, however, this is impossible, for much of the heat passes away by radiation. The calculation, therefore, only serves to gives the highest limit of temperature. Furnace temperature or flue temperature may, in practice, be determined (1) by testing with samples of different metals to discover which one is just melted, when the temperature will be the melting point of that metal; (2) by a pyrometer, one form of which is constructed so that the electrical resistance of platinum may be measured at the furnace temperature; (3) by a calorimeter test, a piece of metal being placed for some time in the furnace until it is at the same temperature, and then removed and plunged into cold water, the weights of metal and water and the temperature of the latter being known. This last is sometimes modified by taking a live coal from the fire and plunging it into cold water, the specific heat of carbon at ordinary temperatures being assumed to be that of the live coal. It seems probable that the surface temperature of a glowing fire does not fall below 1,300°F., but that the highest point to which it may rise depends upon the manner in which the heat is disposed of. Heat passes away from the fire in two ways: by radiation and by convection; and it is the proportion of these to one another which affects the temperature. If the fire is surrounded entirely by a metal surface, on the other side of which there is relatively cold water, practically all the radiation will be absorbed through this surface, while, on the other hand, if the fire is completely surrounded by fire brick, which will become heated to nearly the temperature of the fire, nearly all the heat will be reflected back to the fire, and the temperature of the latter will accordingly become higher than in the former case. In internally fired boilers, in which there is no brick lining to the combustion chamber, it is probable that with the most rapid combustion the fire temperature does not exceed 2,000°F., while in externally fired boilers, where the fire is largely surrounded by brick setting, the furnace temperature may attain or even exceed 3,000°F., the fuel in both cases being assumed to be coal or coke.

Radiation.—Flame.—In order that heat may be absorbed into the boiler water by radiation, it is necessary that there should be a clear straight line from the source of radiation to the heating surface through which the rays are to pass. The source of radiation may be either the fuel itself, or flame, or heated brickwork. The proportion of heat which passes into the water in this way varies rapidly with the furnace temperature, and slightly with the temperature of the heating surface. Thus, in some trials by M. Péclet, it was found that with a furnace temperature of 1,500°F. and a temperature of heating surface of 350°F., about 82,800 heat units were radiated per hour from each square foot of glowing fuel; whereas, when the furnace temperature rose to 2000°F., while that of the surface of metal remained unchanged, the radiation amounted to 693,580 heat units in the same time. In general, the number of B.T.U. radiated from 1 sq. ft. of glowing fuel per hour is given by the following formula, where θ is the temperature of the surface of the fuel, and t that of the heating surface surrounding the combustion chamber:—

$$\text{B.T.U.} = 144\, k^{\theta}\, (k^{t} - 1). \quad . \quad . \quad . \quad (82)$$

The value of k, where the fuel is clean coal or coke, is 1·00425. Usually, the proportion of furnace heat which passes away by radiation varies from ½ to ¾ of the total heat, where coal or coke is used; the remainder of the heat being carried away by convection by the hot gases. Since so large a proportion escapes by the former process, it is very desirable that the radiant energy from the fire should encounter useful heating surface in all directions, or at any rate in as many directions as possible. This can best be attained by placing the fire inside the boiler, so that water will entirely envelop it, except where the fire-door and ash-pit are necessarily placed. It may, however, to a certain extent, be attained by placing the fire externally to the boiler, but in a setting of fire brick which by its reverberatory action will reflect most of the heat on to the useful heating surface. Fire brick is not a perfect non-conductor of heat, however, so that by this method it is inevitable that some of the heat will be conducted wastefully away. Experience shows that a square foot of useful heating surface, when exposed to the direct radiation of the fire, will absorb very much more heat per hour than when merely in contact with the escaping hot gases, even though the temperature of these hot gases may be very nearly as high as that of the fire. The first to put this to practical test was Mr. Robert Stephenson, of railway fame, who found that he could get 16 times the rate of evaporation from a square foot of surface in a locomotive fire-box, exposed to the fire, than was to be obtained from an equal area of tube-surface, not exposed to direct radiation. Every trial at a later date has but confirmed Stephenson's results, though the actual ratio of the evaporative values may differ in different types of furnaces. The advisability of directly exposing as much useful surface as possible to radiation is at once established; for, for every square foot thus exposed several square feet in other parts of the boiler may be dispensed with. It is on this account that flame plays so useful a part in steam raising. Every glowing particle of carbon in the flame acts as a centre of radiation; so that the flame, in its passage along the flues, carries to parts remote from the fire a means of obtaining radiant heat, and thus enhances their evaporative value.

With certain classes of fuels which are liable to develop smoke, it is sometimes found to be impracticable to directly rob them of their heat of combustion by taking the radiation straight from the fire into the water. The process lowers the fire temperature, and thereby tends to hinder the combustion, with the result that smoke is liable to be produced in large amounts. Some engineers have even gone to the extent of advocating the use of brick-lined combustion chambers to obviate this, for every class of coal; but this is by no means necessary, and it would rob the boiler of its most effective heating surface. There are conditions, however, such as where highly bituminous nuts or slack is fired by hand, under which it may be advisable to completely envelop the fire in a reverberatory chamber. An example of such a combustion chamber is given in Fig. 15, which shows a recent modification of a Babcock and Wilcox boiler, adapted to the consumption of very smoky fuel. Immediately over the grate is the lowest layer of water tubes, and upon these tubes there is built up a layer of fire tile, with an opening at the bridge end for the passage of the gases upwards to the upper combustion chamber. Over the further end of this upper chamber there is a similar layer of fire tile, built upon a layer of water tubes; and it is not until the gases have wended their way through both these reverberatory chambers that they can pass through the layers of tubes. The enhanced combustion chamber temperature tends to ensure perfect combustion of the volatile fuel before it reaches the colder metal surface of the ordinary tubes. It is very doubtful if such good results could be obtained in a brick-lined combustion chamber as in an open chamber; for if the fuel is too smoky for hand-firing, one has always two expedients at hand, the one is to mix the coal with a drier quality, the other is to adopt mechanical stoking.

Convection.—The heat which is conveyed from the glowing fuel by the gases is distributed in the following way. A small portion of it will pass through the heating surface over the fire, but the greater portion will pass over the bridge. Of this greater portion, some will be absorbed through the heating surfaces along the length of the flues; either for passage into the water, or for conduction to the outside of the setting and final loss by radiation. The rest of the heat will pass up the chimney, and will maintain the draught. It should be observed that in some cases a portion of the useful heating surface belongs, not to the boiler itself, but to an economiser

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

affixed to it; the action on the furnace gases being, however, the same in both cases. Recognising that some of the convection heat is necessarily directed up the chimney, we have now to consider how best to abstract the remainder from the rapidly moving hot gases. We find that this heat is abstracted under two conditions of the gas relatively to the surface to which it imparts the heat: (1) during gliding motion of the gas over the surface, (2) during impingement upon the surface at or nearly at a right angle. Assuming, for simplicity's sake, that the heating surface itself is at a constant temperature which is very much lower than that of the hot gas, we will compare these two conditions. During perfect gliding the gas travels in unvarying stratification parallel to to the surface; in practice, gliding only approximates to this. The resulting tendency is to abstract heat only from the stratum of hot gas in immediate contact with the cold surface, the other strata losing heat only by slow conduction through this cooled inner stratum. As a consequence, the greater portion of the convected heat is thermally insulated from the cold surface; and the chimney gases escape at too high a temperature, while too little water is evaporated. On the other hand, if the hot gas impinges normally on the cold surface, the particles of gas as they come into contact with that surface will be robbed of their heat, and they will also be

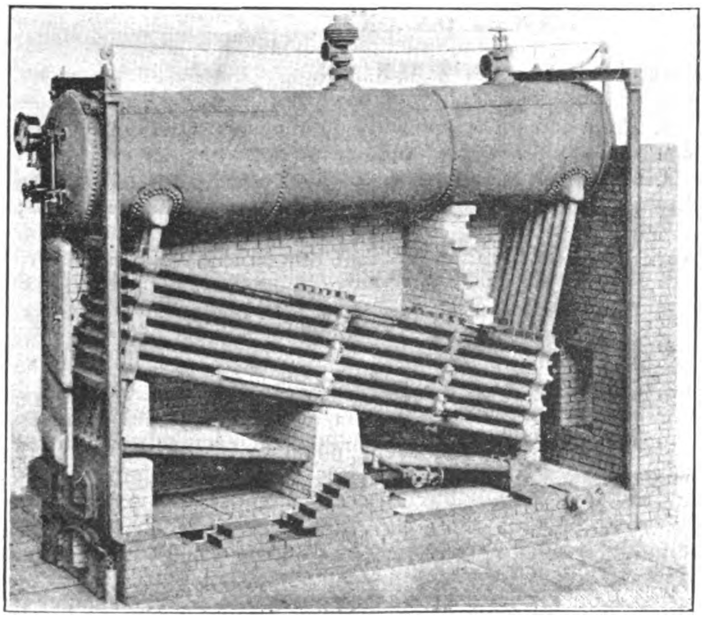

Fig. 15.—Babcock-Wilcox Boiler, fitted with "Scotch Furnace."

deflected at a sufficient angle to cause them to recede some distance from the surface, Thus, fresh heated portions of the gas continually strike the surface, and the rate of absorption of heat is rapid. The perfection of this action depends to a great extent upon the velocity of impingement. If the hot gases strike feebly the cold surface, a cushion of very much colder gas will instantly be formed between the hotter portions of the gas and the cold surface. It is on this account that the thermal absorption by surfaces directly exposed to the impingement of flame is so much lower than that indicated by theoretical calculation. The more rapid the impingement, the greater is the rate of heat absorption. It must be remarked here, however, that a very rapid flame impingement is liable to become injurious to the metal plates, through unequal and excessive expansion of the metal.

When we combine the effects of gliding gases with those of impinging gases, we have a very practical mode of abstracting convected furnace heat. By the interposition of bafflers, the gliding gases are frequently churned up, and fresh portions of hot gas are brought into contact with the cold surface, and in many boilers these bafflers constitute effective heating surfaces, impinging upon which, the gases are led to give up an extra amount of heat besides becoming intermixed. Another mode of reducing the loss of heat due to stratification of heated layers, is to arrange the heating surfaces, parallel to which the gases are to move, so that the mean distance of the gas particles from them is as small as possible. This is done in the locomotive type of boiler, for example, by subdividing the gases in a large number of parallel flue-tubes. To ensure efficient absorption of convection heat it is also necessary to provide that the hot gases shall remain for a considerable time in contact with the boiler surfaces; and to ensure this the gases must be made to travel through a sufficient length of flue at not too high a velocity. The actual length of the path taken by the gases, between the grate and the end damper will generally depend on the type of boiler. In locomotive return-tube and water-tube boilers the distance is small; while in boilers of the Cornish or Lancashire type it may be from 6 to 12 times greater. Moreover, in the locomotive type of boiler the velocity of the gases is often from 3 to 8 times more rapid than in the internal and external flues of boilers set in brickwork.

Heating Surfaces.—We may now direct our attention to what goes on in the boiler portion of the steam generator; and it will be convenient to consider first of all the manner in which the heat is disposed of by the useful heating surfaces. It was pointed out on page 409, Vol. XXXII., that it is impossible to calculate the heat-transference through a boiler heating surface solely upon the data supplied by the difference in temperature between the hot gas and the water and the thermal conductivity of the metal plate. One reason for this has just noticed; we may now mention some others. Firstly, the been temperature of the water stratum in contact with the surface is not constant, nor is it the same as that of the stratum immediately beyond it. Secondly, the plate usually consists of other materials than the mere metal, being incrusted on one side with soot and on the other side with calcareous and saline deposits. There is a well-worn fallacy, perpetuated in numerous text-books, to the effect that if the value of a horizontal heating surface transmitting heat to water above it be taken as unity, then a vertical surface will have a value of only one-half, while a horizontal surface with water below it will have zero value. This, in respect to boiler surfaces, is a complete fallacy; for it is possible to obtain as much heat through a vertical surface as through a horizontal one, provided that precautions are taken to prevent the accumulation of cold gas on its one side or of hot water on its other side. The value of any given heating surface is a function of the gas and water circulations on either side of it; and, apart from radiation, it will be high or low just in proportion as those circulations are properly or improperly designed. The object of water circulation is, to constantly bring fresh cool portions of water to the surfaces to replace the water just heated; just as the object of gas circulation in the furnace is to constantly bring fresh hot portions of gas to the surfaces to replace the gas just cooled. In the boiler, circulation is produced by so arranging the heating surfaces that the heated water can freely rise to the water surface, giving place to the colder portions of water, which will descend. It is caused by the difference in specific gravity produced by heating and expanding water; and the rapidity of the circulation will depend on the ratio of the moving force thus developed to the mass of water which must be set in motion. Rapid circulation is, therefore, obtained by designing the boiler so that its total useful heating surface shall be large as compared with the mass of water in the boiler shell. The usual allowance of heating surface, in boilers for ordinary work, varies from one square foot per 2,500 B.T.U. per hour, to one square foot per 5,000 B.T.U. per hour; although under high draught it is possible to transmit heat very much more rapidly. In boilers for electric power purposes, where it is necessary to rely upon the boiler plant for a considerable excess of its normal steaming rate during a short time every day, it is well to see that both the boiler and economiser surfaces are ample; and for this purpose it would be well to allow not more than 3,000 B.T.U. per square foot of boiler surface per hour, as the normal rate of transmission. It is customary to express the heating surface in a boiler in terms of its grate area. This, taken by itself, is a misleading datum, or no datum at all; but when the normal draught and rate of combustion on the grate have also been specified, it furnishes a

Digitized by Google

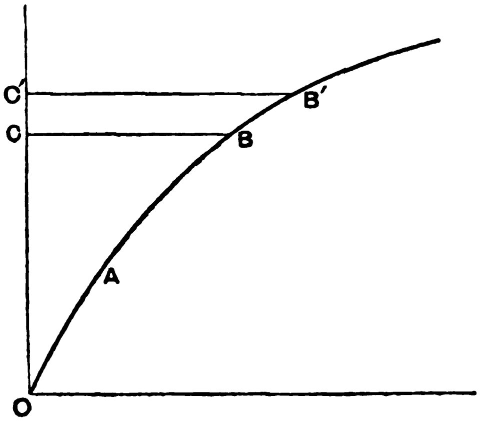
convenient guide to the steaming capacity of the boiler. In early days it was considered sufficient to allow a heating surface equal to 30 times the grate area ; but it must not be forgotten that at those times slower fires were burned under much lower draughts, as well as that a high economy was not expected. Boilers such as are used for electric power purposes are generally provided with heating surface amounting to from 40 to 55 times the grate area, under ordinary draughts ; no account being taken of the surface of the economiser, which, if included, would raise the total heating surface to from 90 to 120 times the grate area. Locomotive boilers under steam blast draught are provided with a heating surface some 100 to 150 times the grate area.

(To be continued.)

ON THE FORCE AN ELECTRO-MAGNET EXERTS ON ITS ARMATURE.

BY JOHN HOPKINSON, F.R.S.

1. Let O A B (Fig. 1) be the characteristic of an electromagnet in a given position of the armature, that is, the curve in which the ordinates are total inductions and the abscissæ are the corresponding magnetising forces.*



The work done in magnetising the field of the magnet is the area O A B C divided by 4π. Thus stated, this is almost obvious. For let T be the time taken for the induction to increase from O C to O C'.

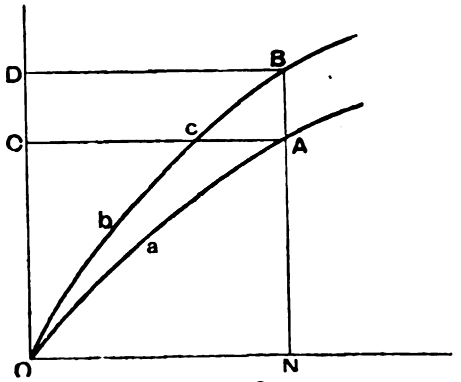


FIG. 2.

The electromotive force exerted by the electromagnet on the circuit is C C'/T × number of convolutions. The work done by this electromotive force in time T is C C'/T × number of convolutions × current × T = C C' × $\frac{\text{magnetising force}}{4\pi}$ = area C B B' C'/4π.

2. Consider one electromagnet with a movable armature. Let OaA (Fig. 2) and ObB be the characteristics of the electromagnet in two positions of the armature. Suppose a current of magnetising force, O N, to be circulating in the magnet, the current being maintained constant, let the armature be moved from position A to position B, in making this movement the magnet will do mechanical work in moving the armature, it will also receive work from the current, as it will exert an electromotive force opposed to the current. Now pass through the following steps: first, make the current work done by the current is O a A C/4π ; next, move the armature work done by the current C A B D/4π ; lastly, unmake the current work done on the current by the magnet is O b B D/4π, and the net work done by the current is O a A B b/4π, and this must be equal to the mechanical work done upon the armature.

Thus if we know, either by calculation or experiment, the characteristic of the electromagnet for various positions of the armature, we know the mechanical work done in moving from one position to another with a constant current in the magnet, and hence the force tending to cause that displacement.

When the distance between A and B is small, the area A B c is small of the second order, and the work done is the area O a A c b.

3. If the space between the armature and magnet is non-magnetisable, and if the magnetising force in the armature be neglected, A c is proportional to A N. Hence area O a A c B = $\frac{1}{2}$ A c . A N.

Now A c = A N × change in ratio magnetic force/total induction

$$= \text{A N} \times \delta \,.\, \text{O N/A N};$$

$$\text{work done} = \frac{1}{8\pi} \text{A N}^2 \delta \,.\, \text{O N/A N}.$$

4. From this we very readily obtain the well-known expression for the tension along the lines of force.

Let the lines of force all be parallel, and let there be a small displacement of the armature δl parallel to the lines of force;

$$\text{work done} = \frac{1}{8\pi} \text{A N}^2 \frac{\delta l}{\text{A}}, \text{ A being the area,}$$

$$= \frac{1}{8\pi} \text{A} \,.\, \delta l \,.\, \text{intensity of induction}^2;$$

$$\text{force} = \frac{1}{8\pi} \,.\, \text{A} \,.\, \text{intensity of induction}^2.$$

5. Consider the case where induction is proportional to the magnetising force, *i.e.*, where there is a coefficient of self-induction, in this case,

$$\text{induction} = \frac{1}{4\pi} \,.\, \frac{\text{L}}{n^2} \,.\, \text{magnetising force}$$

$$= \frac{\text{L}\,x}{n}$$

where x is current, L coefficient of self-induction, and n the turns in the magnet,

$$\text{mechanical work done} = -\frac{1}{8\pi} \,.\, \frac{\text{L}^2 x^2}{n^2} \,.\, \delta \frac{4\pi n x}{\frac{\text{L}\,x}{n}} = \tfrac{1}{2} x^2 \delta \text{L}.$$

The work done by the current is $x^2 \delta$ L, and of this half goes in work on the armature, half in increasing the moment of the magnet.

6. The curves of induction may be determined experimentally with a ballistic galvanometer, but on this the natural criticism would be that it would be as easy to measure the force directly. Or they may be determined *à priori* to varying degrees of accuracy by methods analogous to those I introduced for predetermining the characteristics of dynamo machines.

If the inductions and currents are in absolute units the work and force will be measured respectively in ergs and dynes.

* By magnetising force I here mean line integral of magnetising force

Search Lights and Coast Defence.—The Royal Engineers have completed a system of electric search lights for illuminating the Solent at night, thus affording protection against night attacks, and measures have already been taken to defend the entrance to Portsmouth Harbour by stretching a double line of wire hawsers from shore to shore.

ON A SYNCHRONOUS ALTERNATE-CURRENT ELECTRIC MOTOR.*

BY GALILEO FERRARIS.

In a memoir recently accepted by this class for publication in the academical volumes,† I expounded a method for the treatment of rotating and alternating vectors, and showed, by some applications, its possible utility with regard to many phenomena, and also with regard to the clear and sufficiently elementary explanation of the fundamental properties of many electro-technical constructions.

In this memoir I confined myself to applying the new method to the study of the chief forms of alternate-current motors now in use. But the method also foreshadows the possibility of new combinations, and I believe that it will be not undesirable to point out one of these combinations which is capable of practical applications.

The method expounded in the memoir referred to is based upon the three following propositions :—

1. A sinusoidal alternating vector of fixed direction may always be considered as the resultant of two equal vectors, one of which rotates towards the right and the other towards the left, with the same period. The period of the two rotating vectors is equal to that of the alternating vector, and their common constant length is equal to half the amplitude of the alternating vector itself.

2. Given two groups of vectors, and supposing that at a given instant a is the length of one of the vectors of the first group, b the length of one of the second group, A the instantaneous value of the resultant vector of group a, B that of the resultant of group b, ϕ the angle contained between a vector a and a vector b, and Φ the angle between A and B, then

$$\Sigma\, a\, b \cos \phi = A\, B \cos \Phi$$
$$\Sigma\, a\, b \sin \phi = A\, B \sin \Phi.$$

3. Let a and b be two vectors rotating with the frequencies m and n; these frequencies are considered to have the same or opposite signs, according as the rotations take place in the same or in opposite directions. ϕ represents the angle (a function of the time) which the vectors make with each other. Then, if $m = n$, the products $a\, b \cos \phi$ and $a\, b \sin \phi$ have constant values. If m and n are not equal, these products are variable, and their mean value, calculated for a time equal to a multiple of $1/(m - n)$, or for a long time as compared with $1/(m - n)$, is equal to zero, or is very small.

By means of these propositions, I have, in the memoir referred to, presented the theory of an ordinary alternate-current synchronous motor in the following elementary form. The motor is simply an ordinary alternator; and if for simplicity we suppose it to be bipolar, it reduces itself to an armature consisting of a coil with parallel windings rotating in a magnetic field. The armature conducts an alternating current of frequency n, and the magnetic field, produced by magnets excited by a continuous current, is constant. The alternating current of the armature is equivalent to a magnet whose magnetic moment may be represented by an alternating vector whose direction is that of the axis of the coil, and whose length is equal to the product of the total surface of the coil multiplied by the current intensity in absolute electromagnetic measure. This alternating vector may be decomposed into two vectors, one of which, d, rotates towards the right, and the other, s, towards the left, their frequencies, referred to the armature considered as fixed, being $+ n$ and $- n$ respectively. If the armature rotates with the frequency $+ n$, the two rotating vectors rotate in space with the velocities $n + n$ and $n - n$; the first therefore rotates with a frequency double that of the armature, and the second remains immovable in a fixed direction, which makes a constant and definite angle ϕ with the direction of the magnetic field. The moment of the couple exercised by the fixed magnetic field upon the rotating magnet d has a mean value equal to zero, but that of the couple exerted upon s has a constant value. If $\mathfrak{B}$ represents the constant value of the induction in the magnetic field, the moment of the couple is

$$\mathfrak{B}\, s \sin \phi.$$

The couple tends to close up the angle ϕ. It aids or resists the motion according as the fixed direction of s, which is that of the axis of the armature at the instant of its greatest current intensity, is on the left or the right hand of the direction of $\mathfrak{B}$. In the first case, the apparatus represents an electric motor, in the second case, a dynamo.

Now let us consider the same apparatus on the supposition that the magnetic field in which the armature turns, instead of being constant, is a field alternating with frequency n equal to that of the current of the armature itself. Let us, in fact, suppose that the field magnets are no longer excited by a continuous current, but by the alternating current flowing through the armature, or by another alternate current of the same frequency. We can easily show that in this case also the apparatus can be made to act as a dynamo or as a synchronous motor, and that for this purpose it is sufficient to make the armature rotate with a velocity such that it makes $2n$ revolutions per second.

As a matter of fact, the alternating magnetic field is equivalent to two fields, one of which, D, rotates to the right, the other, S, to the left, with the frequencies $+n$ and $-n$. Let us then give the armature a rotation to the right, say, with a frequency $2n$. Of the two rotating magnets d and s, to which the armature may be supposed equivalent, d will then turn in space with a frequency $2n + n = 3n$; the other, s, will turn in the same direction with $2n - n = n$. The mean value of the moments of the couples exerted by d upon D and S, and that of S upon s will be zero. But this will not be the case for the couple exerted by D upon s, for both s and D will rotate to the right with the same frequency, and will, therefore, maintain a constant angular distance ϕ. Hence the mutual couple will have a constant moment. It will tend to close up the angle ϕ. The apparatus will work as a dynamo, or as a motor, according as s precedes or follows D.

Thus we have a synchronous motor with an alternating field. The theory, which I have expounded in an elementary form for the simple case of a bipolar apparatus, is extended without difficulty to the case of a multipolar apparatus.

This motor, like all synchronous motors, does not begin to work unless before switching on the current it is given the standard velocity, and this is actually equal to double the velocity at which it would work if its field were excited by a constant current. But it is not difficult to conceive devices for starting the motor analogous to those already in use for motors of other constructions. Thus, for instance, a motor with $4n$ poles might be provided with a commutator, by means of which it could, when starting, be made to work as a two-phase motor with $2n$ poles only, by passing through $2n$ coils a current of different phase with respect to that passing through the other $2n$ coils alternating with the first. By this means the armature may be given a velocity closely approaching that of synchronism in the $2n$ pole machine, which is exactly double that necessary for synchronism in the $4n$ pole machine. When that velocity is nearly reached all the $4n$ coils are, by means of the commutator, put in series, in parallel, or in groups in the same circuit, and the motor begins to work normally as a synchronous motor in the manner explained. For the production of the auxiliary current of different phase for the purpose of starting, the device employed by Brown for single-phase synchronous motors may be used, or other similar well-known contrivances.

NOW READY.

Volume XXXII. of "THE ELECTRICIAN," price 13/6; post free, 13/6; abroad, carriage extra.

Cases for binding Volume XXXII., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; and Mr. Alexander Siemens, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

ELECTRICITY SUPPLY IN LONDON.

WE publish this week our annual analysis of the capital and revenue accounts of the statutory electricity supply concerns at present at work in the metropolis. Some care has been taken to ensure arithmetical accuracy, but originality, we frankly confess, need not be looked for. Figures, it is deprecatingly exclaimed whenever the subject of statistics is introduced, can be made to prove anything, and this sententious aphorism is usually quite sufficient to nip the tender budding efforts of many an embryo statistician, a result for which we have every reason to be thankful. The dictum, nevertheless, contains a flaw. Figures can be made to prove something. If a few obvious arithmetical operations show that the Belgravia and Mayfair Electricity Supply Corporation has a coal bill of only 0·5d. per unit sold, whilst the Upper Tooting Company's figure is 3·6d., there is really no denying that one concern spends more than seven times what the other does on coal per unit. So far the much-maligned statistician, always provided arithmetical fate has been kind to him, is in an impregnable position. Should he, however, desire to proceed one step further on his analytical career and draw the moral, let him refrain! Every district has its peculiarities and difficulties which no numeric can express; every company's system is, of course, the best; beware of hinting otherwise. To prove that one country has ten times the inhabitants per square mile that another has may or may not be a useful performance; at any rate, it is more or less of a

Digitized by Google

fact. To "prove" therefrom that one country has ten times the brain power per unit area is perilous; there are heads and heads. It has, however, been our aim to *prove* nothing, to base our multitudinous percentages and decimals of a penny wholly and solely upon the figures given by the respective companies in their Board of Trade returns, and to deduce results likely to be useful to the engineer rather than to the financier. Whenever any important item has appeared likely to mislead, attention has been called in a footnote to its dubious character, but no attempt has been made to arrive at an approximation to the absolutely correct by the application of an arbitrary coefficient of "involuntary mendacity." In two instances, however, circumstances duly recorded in appropriate footnotes, have obliged us to indulge, much against our will, in a little editorial estimating; we trust the result will be found tolerably satisfactory.

Up to December 31st last, the ten companies and one Vestry engaged in the electricity supply business in London, had spent between them close upon 3½ millions sterling, an increase of some 34 per cent. upon the figure for 1892, the major portion being due to the City of London Company. By far the most important contributor to this total is the London Electric Supply Corporation with its capital outlay of £851,134. The average capital expended per lamp connected now stands at £5; the best individual figure being the £2. 10s. of the Chelsea Company—the Kensington, Westminster, and House-to-House Companies following close upon its heels. In regard to mains, the Notting Hill Company would appear to have made the handsomest provision for future contingencies, no less than 44 per cent. of its total capital being locked up in copper and conduit; the Westminster Company, however, is almost as sanguine, and makes a good second with 42½ per cent. of its money expended on mains.

Turning to the revenue accounts, it will be seen that the aggregate gross income for 1893 amounted to £285,061, and the total units metered to 9,889,794, the increase in either case being about 25 per cent. over the totals for 1892. Deducting the revenue derived from meter rents, transfer fees and such like adventitious aids, the total income arising from the sale of current will be found to be something over ¼ million sterling, showing that the average market price of the Board of Trade unit in London last year was 6·38d. The data at our disposal also enable us to deduce the figure of 7s. 6d. for the average return per lamp connected; owing, however, to the large additions which still continue to be made late in each year to the lamp connection, the 8-candle lamp is, as a matter of fact, a somewhat more fruitful source of revenue than this. The coal bill of the metropolitan electricity supply concerns amounted last year to £54,752, a figure which works out at 1·328d. per unit sold, or 10 per cent. less than in 1892. The Kensington Company wins the prize for the lowest coal

[1] Of this sum nearly £123,000 was paid for the land, buildings, plant, mains, &c., when the limited liability company was formed; the balance of £76,000 has been subsequently expended on these items.

[2] Includes property subject to £800 mortgage.

[3] This item includes the sum of £10,237 paid for the Cadogan Electric Light Company's business and plant.

[4] In order to make the various items of the accounts of this Company fairly comparable with the corresponding items in the accounts of other companies not engaged in public lighting or in telephone tube laying, all charges debited to these two enterprises have been placed as far as possible under the miscellaneous column; the expenditure on machinery, however, includes the outlay on arc lighters, and that on mains the outlay on the street lamp leads. The following are amongst the more important items of the miscellaneous expenditure:—Street lamps, £24,382; rents, rates, taxes, &c., charged to capital, £24,466; telephone tubes, £68,887; Southwark Order and mains, £8,592.

[5] This sum includes £7,500 paid in connection with patent rights and covenants with Managing Director.

[6] This sum is made up of £15,000 for purchase of the Kensington Court Company, £7,346 paid for the South Kensington Order, £2,077, cost of the Provisional Order.

[7] This is the total capital expenditure up to date, less £2,692 written off; so that the actual total amount which has been spent on capital account is £853,826.

[8] The chief components of this huge total are £249,107 paid for the Grosvenor Gallery business; £30,000 cost of redeeming debentures; £10,311 preliminary expenses.

[9] This is the total expenditure up to December 31, 1893, *less depreciation*, and as this amounts in all to £11,650 18s. 6d., the total capital outlay since the commencement of the Company has actually been £222,680.

[10] This is the total expenditure on buildings up to December 31, 1893, *less depreciation*, amounting in all to £1,239 17s. 5d.

[11] This is the total expenditure up to December 31, 1893, *less depreciation*, which for plant, machinery, &c. (presumably including mains, meters, and so on), amounts to £10,411.

[12] This sum includes cost of switches and labour.

[13] This includes £7,209 spent in connection with the public lighting.

[14] This sum includes £10,133 paid to the City of Westminster Electrical Syndicate.

[1] This includes £700 set aside for depreciation.
[2] The lighting of this Company's station alone costs £425 per annum.
[3] Wages of men alone included; salaries come under management expenses.
[4] The receipts, expenditure, &c., all relate solely to the Private Lighting business.
[5] This includes sums amounting in all to £2,690 set aside for depreciation, and written off suspense (law) account and preliminary expenses.
[6] As we have received no reply to our request to be supplied with information as to the number of units sold during 1893, we have been compelled to derive the figure from the selling price of the Board of Trade unit, viz., 6d., and the revenue obtained by sale of current per meter and under contract, viz., £23,072. 10s. 8d.
[7] As information as to the number of units sold during 1893 was refused by the Company, the figure given has been derived from the price charged

bill per unit, its figure being 0·74d., the Westminster Company coming next with 0·78d. Of the companies with coal bills trembling on the verge of twopence the less said the better; for no true comparison is possible unless considerations of total output, character of district, and facilities for coal transport are taken into account. An improved type of transformer has already in one case brought about a reduction in this source of expense, and an improved arrangement of the transformers may be reasonably expected to do likewise in other districts.

REVIEWS.

Electromagnetic Theory. Vol. I. By Oliver Heaviside. (London: *The Electrician* Printing and Publishing Company, Limited.)

"The well in which truth is said to reside is a bottomless pit." Thus Mr. Heaviside expresses his belief in the infinity of Nature. It is a characteristic way of putting it, though what is meant may not be quite obvious without somewhat careful consideration. In Heavisidesque, the "practical man" seems to think that science resides in The Bottomless Pit, but certainly Mr. Heaviside does his best to show all men that science is a child of light and not of darkness, even to the "practical man." Nevertheless, it is to be feared that the garb in which this child of light appears here may deter many a practical man from using the light. We must train up a generation instructed in the new ideas with a gradually grown familiarity with the most appropriate terms for electromagnetic descriptions before they will find Mr. Heaviside easy reading. Sentences such as the following require a deal of consideration before they convey much meaning to most minds:—"If we replace our illustrative conductor by an inductor, supporting magnetic induction, and suppose it surrounded by imaginary matter of zero inductivity, and have an impressed gaussage instead of voltage at the terminals, we shall have a flux of induction which will, if the force be weak enough, vary as the force." "The electric current is measured by the magnetic circuitation, or by the circuital gaussage." The practical man would think it better to measure it by an ammeter. The fact is that new sciences require new languages, and that just as the poor handloom weavers were thrown out of work by the introduction of power-looms, so those brought up upon charges of electricity and action at a distance find the more powerful analytical engines of the present rather unwieldy. Sir Francis Drake would probably be quite at sea in a modern warship. The value of an engine, analytical or otherwise, is to be judged not by the difficulty of learning how to work it, but by the work it does, and Mr. Heaviside's engines have done a great deal of work, and in this volume he has tried to put others in possession of the same engines by which he has done his work. It is hardly fair to call them analytical engines, because they are so largely geometrical, but in the larger sense of the word they analyse the phenomena into its component parts in such a way that we can discover how the phenomena work, and invent improvements in our working.

Mr. Heaviside has been greatly impressed with the value to himself of vectorial analysis, and a large part of his work is expressed in terms of it, and he has devoted a considerable part of this book to an introduction to vectorial analysis. It is a pity that, in order to avoid a minus and an S, he should have departed from Hamilton's notation, and have sacrificed an important series of interpretations of the equations that Hamilton's notation includes. The difference is, however, not very serious; in fact, the pity is that for the sake of so little, any change, especially one restricting the use of the calculus, should have been made. It is, any way, to be hoped that those who, in the future, set themselves to study these subjects from the mathematical point of view, will put themselves in possession of ideas and of a means of attack which have been judged to be so very valuable to themselves by leaders of modern science, such as Hamilton and Maxwell. It is not to be expected that all students of electrical science should be able to wield these engines. Division of labour is the essential means of progress. The engine-driver does not try to work the spinning jenny nor to design cards for weaving. It is

during the year for the Board of Trade unit, viz., 7¼d., and from the sum given in the revenue account, under the heading of "sale of current, *less* reserve for doubtful debts, allowances, &c.," viz., £64,312. 8s. 5d.

[8] This sum includes £1,961 set aside for depreciation.

[9] This sum only includes repairs to, and renewals of mains; the salaries paid in connection with distribution work being mixed up with those paid in connection with generating expenses.

[10] This figure, like all the others relating to St. Pancras, include the public lighting; 197,676 units were sold to the public lamps at 6d., including trimming, repairs, &c.

[11] This sum includes an item of £731 for carbons, attendance, and repairs of public lamps.

[12] This total includes £2,900 set aside for depreciation.

sincerely to be hoped that every student of electrical science will not imagine that he could be an Oliver Heaviside; but, on the other hand, it is to be hoped that those who do feel that ambition, and feel that they have that ability, will put themselves in possession of the engines he has used. Without learning to use these engines, any student would have his views of electromagnetics enlarged by a study of the conceptions underlying these engines. Just as a student of physical science should have an elementary and accurate general conception of how steam engines work, so the engineering student should have an elementary and accurate general conception of how the efficiency of steam engines may be calculated so far as the theory is known. Without these elementary general conceptions, intelligent appreciation of the subjects and the prospects of improvement are small.

The number of problems attacked in this volume, and methods of attack, are too many to enumerate. With many interesting digressions into such questions as the depth of the electrified layer on a charged conductor, the cure of the disease of "4 π," discussions of the best working analogies to represent the structure of the ether, and other interesting things that crop up almost in every second paragraph the general current of the book leads from the elementary laws connecting electric and magnetic forces in conductors and non-conductors up to the propagation of waves along wires. It begins with Oersted's observation as to the law of magnetic force round changing electric displacement, and Faraday's observation as to the law of electric force round a changing magnetic displacement, with Ohm's law for conductors of electricity, and Heaviside's law for conductors of magnetism, from these four laws working on Maxwell's grand generalisation as to electric and magnetic displacements the whole fabric of electromagnetics is built up. In order to lead the student from these laws to their application to wave propagation, the effect of a moving electrical charge in producing electric and magnetic forces in its neighbourhood is introduced in the second chapter. This is just the sort of method of attacking the subject that disheartens the ordinary student, and distresses the practical man. "How on earth can he know what would happen when a charge of electricity moves with the velocity of light, and who cares what it would do?" And yet it is just these extraordinary methods of attack that betoken genius and enlarge our views of Nature. In an allied question that has only been once or twice made the subject of experiment, namely, the effect of the motion of the medium on the propagation of waves, Mr. Heaviside has, by his methods of attack, hunted out the cause of an anomalous conclusion obtained by Prof. J. J. Thomson, and has put the matter upon a satisfactory basis. From this he proceeds to discuss the way in which energy is transferred by the ether, and as to the stresses in the field, finishing up Chapter II. with an account of the dreadful epidemic of 4π, which is desimating electromagnetic calculations, and how the disease should be treated in a scientific manner, so as to produce a radical cure. However, while such monstrosities as fields measured by force per square inch are tolerated, and when it is seriously proposed to legalise a value of the ohm, which is not 10^9 C.G.S. units, there seems very little hope that a few 4π's coming in where they should not will cause sufficient general nausea for the scientific and practical world to vomit them forth.

In an appendix to Chapter II. Mr. Heaviside considers various theories that have been proposed as to the structure of the ether. The only one that he considers at all satisfactory is the same as that recently worked at so suggestively by Mr. Larmor in a communication to the Royal Society. This one, however, is rejected as not leading to the Maxwellian stresses and mechanical forces on charged and currented bodies. Mr. Heaviside does not explain his reasons for this statement which seems at variance with Mr. Larmor's Paper, and a further elucidation of the question beyond that given here and on page 258 would be most interesting. In this system magnetic force is a flow, while electric force is of the nature of a twist, the opposite analogy being the one most frequently put forward largely on an inconclusive deduction from the rotation of the plane of polarisation of light by matter when subject to magnetic force.

Chapter III. is an account of vector analysis, which, with the addition of the minus and the S that Mr. Heaviside

Digitized by Google

discards, would make an admirable introduction to the study of quaternions, and as it stands is in most respects much more intelligible than other introductions to this calculus, which can do so much to enlarge the student's ideas as to analysis, geometry, and dynamics. In this chapter is introduced a very complete discussion of the various dynamical analogues that have been suggested for representing the structure of the ether and the motions and elasticities that may represent electromagnetic quantities. It seems probable that no simple analogy is possible, and that electric force and magnetic force are both kinetic, and both accompanied by irrotational and rotational motions. Mr. Heaviside has apparently discussed and disposed of all possible simple theories, and notwithstanding the recussitation of two of them by Prof. Boltzmann and Mr. Larmor, the prospects of a simple solution of the problem seem, on the whole, improbable.

Chapter IV. deals with the propagation of plane electromagnetic waves. This is studied principally with the object of leading up to the case of the propagation of signals in telegraph and telephone wires, a subject that the author has done so much to advance. He shows how the problem must be attacked when it is complicated by dealing with vibrations which are so rapid that the distributed self-induction of the line must be taken account of if we are to obtain an even approximately true solution. When Lord Kelvin originally attacked the problem of transmission of signals by submarine cables, the solution he obtained was one conditioned by the circumstances to which he was applying it. He attacked the problem before him, and did not attack a lot of other problems with which telegraphists at the time were not concerned. In the problem he attacked the most important factors were resistance and capacity, and he did not include in this simple case leakage or self-induction, because they were not of serious importance then. The whole problem of telephony has since acquired energy. In it we are dealing with alternations at the rate of thousands per second, where we were dealing with tens and hundreds per second before. Every electrical engineer knows how impedance is of importance with rapid alternations when it may be practically neglected with few alternations. Every electrical engineer is familiar with the way in which, by a proper balancing of capacity and self-induction, we can transmit electrical energy into a machine which would otherwise hardly respond at all to our alternating impulses. The complete problem of telephone wires is too complicated to attack upon simple principles such as these, but it is to be hoped that some of those who are concerned with the practical problem have sufficient mathematical ability to at least follow the investigations Mr. Heaviside has shown so much genius in inventing and has taken so much pains to work out in detail, so that any person at all conversant with the problem can understand what he states to be the conditions of success in telephony. Mr. Heaviside does not pretend that he has solved the problem in all its details as it may occur in actuality. He specially guards himself against such a supposition by qualifying his premises. He neglects radiation of energy into the surrounding medium and the curvature of the wave surfaces and of the wires; he calls particular attention to the increased resistance of wires to rapidly alternating currents, owing to their imperfect penetration; and although he states that this does not produce any very serious effect on telephony through copper wires, he has not gone into the question with the same degree of detail as he has as to the effects of leakage and self-induction. The effect of this in iron wires is so great that they have been discarded as telephone wires in America where long-distance telephony has been very largely tried. This is an example of one of the questions which was quite immaterial in the problem Lord Kelvin originally attacked, but which is of great importance in telephoning through iron wires, and must ultimately be appreciated by practical telegraphists, even though they for a time sneer at those whose bodily infirmities prevent them from helping the advance of mankind in any other way than by using their powerful intellects to solve the problems that at present require solution, in order that the practical man may improve his practice.

G. F. F.G.

ON THE EFFECT OF LEAKAGE ON WAVE PROPAGATION IN TELEGRAPH WIRES; OR, MR. OLIVER HEAVISIDE'S THEORY EXPLAINED BY ANALOGY.

BY GEO. FRAS. FITZGERALD, M.A., SC.D., F.R.S., F.T.C.D.

The first thing to understand is what sort of thing a series of electromagnetic waves is when going along a wire. They are sent as a series of alternating electric currents in the wire: just as a series of alternating compressions and rarefactions can be sent along a speaking tube. Of course, the analogy is not perfect. On the face of it we are dealing with something going on inside the tube, while we are obviously dealing with things going on outside the wire, there is magnetic force in circles round the current and electric force out from the wire wherever the electric pressure is higher than that of the earth, and in towards the wire where the pressure is lower than that of the earth. In the case of the wire, then, we are dealing with a case of lines of magnetic force in circles round the wire, and with radial lines of electric force diverging from the wire. Wherever the current is great the magnetic force will be great, and wherever the electric pressure is great then the electric forces will be great. The waves consist of alternations of current in opposite directions, which are propagated along the wires in much the same way as the vibrations of the molecules of air in a tube are transmitted along the tube. We may look upon the compressions and rarefactions of the air as analogous to the electric pressures positive and negative in the wire, and we may look upon the currents of air as it vibrates backwards and forwards, as analogous to the backwards and forwards electric currents. Of course, the analogy is somewhat rough, but on account of the want of familiarity of the ordinary student with electromagnetic waves, a rough analogy may help him to reason about these waves, or at least to follow the reasoning that is applicable to electromagnetic waves. Now in all cases of wave propagation there are certain very important conditions that must be fulfilled at each point in order that waves may be transmitted without reflection. In the case of sound waves, the ratio of the velocity of the particle to the velocity of the wave must be equal to the compression at each point. Everybody is familiar, in the case of light, with reflection of waves by a change in the nature of the medium and by obstacles placed in its way. A sound wave is similarly reflected by an obstacle. At the surface of the obstacle the motion of each particle is not all transmitted on to the next particles. We all know the way in which one ball hitting an equal one is brought to rest, and its motion transferred to the hit ball. If they are not equally massive, or if the hit ball is constrained by being gummed to the table, the motion is *not* all transferred, the hitting ball does not stand still after the impact, but is in a condition to send back motion to others behind it. Similarly when waves meet obstacles, their energy is not all transferred on to the parts of the medium in front, they retain some and send it back by the way it came. In the case of the balls hitting one another there must be an important relation between their mutual pressure and their velocities of motion in order that the energy of the hitting ball may be all transferred to the hit one; and in the case of waves being transmitted through air, there must be an important relation at each point of the wave between compression at that point and the velocity of the particles of air at the place, in order that all the energy at each point may be transferred forwards and none backwards. In the case of the electromagnetic waves we must have a corresponding relation between the electric pressures and the electric currents in order that a wave be transmitted all forwards and that there be no reflections. Now, in the case of the balls hitting one another, there are two ways in which the hitting ball may fail to give up all its energy to the hit one. This latter may be either too heavy or too light; it may be either too hard to move or too easily moved. In either case it will fail to absorb all the energy of the hitting ball. Similarly, in the case of an air-wave in a tube. A reflection may result either from an obstacle that prevents the

Digitized by Google

air from moving, or from a hole in the tube that allows too great freedom of motion; in either case there will be reflection. These two causes do not make exactly the same kind of reflected wave, they produce what books on sound call reflection, without and with change of sign. In the case of an obstacle, a compression is reflected as a compression, while in the case of a hole, a compression produces a reflected rarefaction. In the case of electric waves, we can have reflected waves produced by obstacles which oppose the electric currents, or by leaks which relieve the electric pressures which exactly correspond to the two ways in which reflected waves are produced in tubes by interfering with one or other of the two things, velocity and compression, which must keep up a certain proportion to one another in order that waves be propagated all forwards without any going backwards. Now it is pretty evident that if there is an obstacle in a tube we might compensate for it by making a hole near it, and although the result would be that some of the energy of the wave would undoubtedly be wasted, still we would stop the effects of reflection. If there were a number of obstacles they will generally confuse a wave sent along a tube, because each will reflect forwards parts of the waves reflected to them by the others, and the result will be that a series of simple waves going along the tube will be quite unrecognisable when they reach the other end. Now, an ordinary speaking tube is affected by this, though not to any very serious degree. Every point of the tube offers some frictional resistance to the vibrations of the particles of air inside it, and as a consequence a single sudden impulse sent into the tube does not reach the other end as it went in, but is drawn out by what comes to the same thing as a whole series of multiple reflections that are taking place along the tube. Now, from our study of the nature of the reflection produced by the resistance of an obstacle, we saw that it might be neutralised by a corresponding leak or hole in the tube, so that we conclude that the distortion of the impulse we sent along the tube might be corrected by making the tube judiciously leaky, and that, as a result, a sudden impulse at one end would arrive at the other end as a sudden impluse, though, no doubt, it would be very much weaker than it went in. Now, what we want in the case of speech is that the waves that come out of the tube shall be the same shape as those that go in. Otherwise, our speech will be muddly and unintelligible, as it is in other cases of multiple reflections, and we might very often be quite willing to sacrifice loudness for the sake of distinctness.

Just the analogous things occur in telephoning through wires. The current of electricity is resisted by the want of perfect conductivity in the wire, and the effect of this is to draw out a sudden impulse by what is the same as multiple reflections from a great number of separate resistances, and as these resistances cause reflections by interfering in one way with the proper relation between the current and pressure, so we can compensate for them by relieving the pressure by a judicious amount of leakage. This is a nearly complete analogy between the waves in the tube and the electric waves in the space around the wires. There are, however, some further points that can be illustrated. In the first place we have dealt with the resistance at the surface of the tube, as if it were a resistance to the whole wave. This is only approximately true, and the approximation would be less and less accurate if we were dealing with very short waves in very large tubes. In the electromagnetic case we have made a similar simplification. Events are really occurring in the medium round the wire, and the effect of a resistance in the wire does not extend instantaneously all over the face of the wave, so that there are a set of phenomena due to this which have been neglected. We have, as it were, summed up all that is going on round the wire in a shorthand description when we spoke of it as electric currents and electric pressures in the wire. The electric current is a shorthand description of a complicated state of affairs partly inside and partly outside the wire, and the same is true of the term electric pressure in the wire. These shorthand descriptions are very helpful, especially in working out analogies, but we must take care to recollect that they are shorthand compendiums of a really complicated state of affairs, and that our analogies do not generally extend to the complications.

It may be worth while explaining how this investigation merges into the case that Lord Kelvin originally attacked, namely, that of comparatively slow alternations of current being driven into a cable. This case is like trying to blow air through a long tube. If we send a sudden puff of air it will be transmitted like a sound wave; but if we keep on a steady pressure, we will gradually get up a uniform blast, the pressure in the tube will be great at our end and small at the far end; and, if we suddenly stop, the blast at the far end will not suddenly stop, for the compressed air in the tube will escape at both ends for some time. This is just like what happens in a telegraph cable. We apply a high pressure suddenly, but it does not rise equally suddenly at the far end. We must wait until enough air has run in at the near end to produce the increased pressure of air inside that is required to drive as much along and out of the tube as we drive in, the pressure will rise until this equilibrium of flow is attained, and until then the flow at the far end will be less than that at the near end. In a case of this kind, it is evidently undesirable to have a large capacity in the tube, and, of course, a high resistance is very objectionable. In this case a considerable inertia in the fluid is of little importance, any effect it has is rather detrimental as preventing sudden changes in its velocity. It is quite different in the other case of our dealing with alternations that succeed one another so rapidly that the inertia of the fluid is of great importance. The inertia of the fluid is essential for wave propagation, and with a given velocity backwards and forwards the energy of the wave is proportional to the inertia of the medium. When there is resistance to be overcome, it is all important that we should have plenty of inertia. Everybody knows how hard it is to throw a cork to any distance, while a bullet of the same size, and projected with the same velocity, is hardly stopped by the resistance of the air. This is because the energy of the bullet is initially so much greater than that of the cork, that the same amount being taken from each very soon uses up that of the cork, while it leaves that of the bullet but little changed. Similarly, in the case of waves in tubes. If the resistance of the tube to the motion of hydrogen and of air were the same, which is not accurately true, a wave of given amplitude transmitted by hydrogen would be practically all wiped out long before a wave of the same amplitude in the tube full of air would be. The original energy of the air wave would be much greater than that of the wave in hydrogen, so that it would bear much more energy being taken out of it before it was practically deprived of all its energy. This is the basis of the proposal to increase the self-induction per mile of telephone wires. The self-induction of the wires corresponds to the inertia of the gas in the tube, and if it can be conveniently increased without unduly increasing resistance, and other causes of loss of energy, it may help very much in getting enough energy into the waves to enable them to travel far without serious loss. It may be interesting to point out that some of the "other causes of loss of energy" mentioned above may be illustrated by the air-tube analogy. One of them is induced currents in neighbouring bodies. This may be illustrated roughly by the movements produced in the containing tube. The loss by hysteresis in neighbouring soft iron may be illustrated by one of the ways in which one might try to increase the inertia of the medium in our tube. Suppose one were to try and do so by suspending a number of thin tinfoil plates in the tube which would be carried backwards and forwards by the currents of air particles, and add their inertia to that of the air. If they fitted well, their velocity would be equal to that of the air, and their inertia, of course, might be hundreds of times that of the air. If, however, they did not fit accurately, and if they rubbed against the sides of the tube with a proper law of friction, one could arrange that they tended to attain maximum velocity as the velocity of the air was increased. There would then be introduced effects which would fairly well represent both the want of constancy in the permeability of the iron and its hysteresis, one represented by the non-agreement between the velocity of the air and the plates, and the other by the frictional resistance to the motion of the plates.

In conclusion, it may be worth while calling attention to the general subject of dynamical analogies. They are really on

Digitized by Google

the same footing as the representation of forces by geometry. In just the same way as we can find out the stresses in a structure by drawing lines, we can discover the way a complicated system will move by making a judiciously constructed analogous model. We are only making a practical application of the well-known principle of generalised co-ordinates.

ON THE MAGNETIC DEFLECTION OF CATHODE RAYS.*

BY P. LENARD.

§ 1. When cathode rays traverse a magnetic field, their otherwise rectilinear path becomes in general curved, they are deflected by the magnet. The deflection is not always of the same magnitude in a field of given strength. In the discharge tube, as usually made, the deflection increases with increasing pressure of gas. In this respect the behaviour of cathode rays agrees with that of a current of small negatively charged particles projected from the cathode. The paths of such particles would in fact be curved in a magnetic field, and the more curved the lower the speed; therefore, like the cathode rays, more curved in the denser and more resisting gas than in the more rarefied. This agreement between cathode rays and radiant matter, which is also to be found in other phenomena of the rays, and which, since Crookes' researches, has been regarded by many physicists as holding generally, can in reality be only superficial if the conclusion arrived at in my earlier Paper,† namely, that cathode rays are phenomena in the ether, be correct. That the resemblance is merely superficial in reality, seems to me to be proved by the following experiments, in which the agreement completely fails in this respect, that conditions which must have the greatest influence on the speed of radiant matter appear quite without effect on the amount of deflection

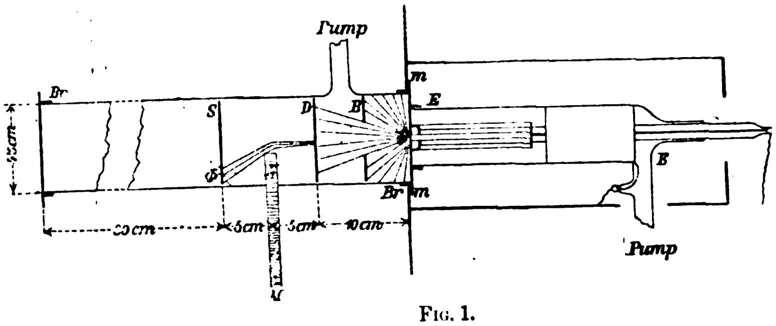

FIG. 1.

of cathode rays in a magnetic field. The experiments show that the amount of magnetic deflection is not in the least affected by the medium in which the rays are observed; that, on the contrary, the capacity for deflection of one and the same kind of cathode ray remains always materially the same in all gases at all pressures with every intensity of ray, and even when the rays have to traverse a metal partition placed in their path; and, on the other hand, that in gases at different pressures different kinds of cathode rays are produced, possessing different capacities for deflection.

§ 2. We produce the cathode rays for our experiments in the discharge-tube already described, E E, Fig. 1, from which they come through the air-tight aluminium window into the observing space. This space is surrounded by the glass-tube Br, which closes tightly on to the window partition *m m*, and it is in connection with a mercury air pump.‡ The observing space can, therefore, be filled with any desired gas at any required pressure. A second mercury pump produces the vacuum in the discharge-tube. In the observing space a movable diaphragm, D, having a hole 1·9mm. in diameter, cuts off a small pencil of rays, which shows itself as a spot of light on the similarly movable phosphorescent screen S. The position of this spot is read on a scale made on the screen itself. If now a small but powerful horseshoe magnet, N M, be brought to a certain position on the tube, and the position of the spot again read off, then the magnetic deflection of the rays is measured by the difference of the two readings. The magnet was always brought to the tube in such a manner that its poles on either side of the tube were as shown in Fig. 1, and the north pole of the magnet was always assumed to be uppermost, and the south pole below the tube. The rays are then directed towards the magnet to the position Φ; the oppositely-directed deflection produced by reversing the poles, was nearly of the same value. The magnet can be easily and surely replaced in this position, for the poles are nearer together than the diameter of the tube; the two poles touch the tube, therefore, and in definite points. A small displacement or rotation of the magnet in any direction from this point does not alter appreciably the amount of the deflection. Large displacements have, of course, appreciable effects. If we displace the magnet by sliding it along the tube from the position shown in Fig. 1 up to the window partition *m m*, the amount of the deflection increases at first slowly, until the magnet has passed the diaphragm D, then decreases again, becoming very small when the magnet arrives at the window partition. This behaviour is explicable on the supposition that the strong field of the magnet is confined to a small space, so that the rays, which come in all directions from the window, are only bent through a given angle just as they come past the magnet and move otherwise almost in straight lines.

The distances of magnet, diaphragm, and screen from one another and from the window assumed in the following as generally used are those shown in the figure; if a displacement is spoken of, both diaphragm, magnet, and screen are moved through equal distances, so that these three movable parts always retain their relative positions. Between window and diaphragm was placed in most cases the blind B, with an opening 17mm. wide. This blind has no influence on the phosphorescent spot or on the deflection, but it prevents the weak diffused illumination of the screen which would otherwise occur because the diaphragm does not fit tightly to the glass tube.

§ 3. Now, suppose all conditions of the phenomenon kept constant, and especially let the pressure of gas in the discharge tube be so regulated, that the spark length which measures the pressure remains always at 2·8cm. Now, while we watch the amount of deflection of the phosphorescent spot in observing space, let the air therein be lowered in pressure from 33mm. to 0·021mm. This considerable alteration of pressure, which is almost a hundred times as great as the difference of pressure within which it has been possible to observe hitherto, the deflection of cathode rays does not cause the smallest definitely observable alteration in the position of the deflected spot. The reduction of pressure was effected in 13 steps, and the amount of deflection observed every time. It varied irregularly, from discharge to discharge, between 9·5mm. and 10·5mm. backwards and forwards; similar variations from discharge to discharge were also observed if the pressure of gas in the observing space remained constant. Higher pressures than 33mm. could naturally not be used, as under those circumstances the phosphorescent spot in the turbid medium was so ill-defined and so large, that its position could not be definitely determined.

§ 4. But if, on the other hand, we keep the pressure of gas in the observing space constant, and alter the pressure in the discharge tube, this has at once a very distinct influence on the position of the deflected spot. The smallest alteration of pressure makes itself evident; even a rise or fall of a few centimetres in the level of the mercury in the pump vessel is sufficient to displace the deflected spot. The same small alteration of the pressure in the discharge tube makes itself observed in the sparking distance, which is a measure of this pressure. Corresponding to an alteration of this sparking distance from 2cm to 4cm. there is an alteration in the amount of the deflection of from 12·2mm. to 8·5mm. Increase of the pressure of gas in the discharge tube has, therefore, as a consequence, an increased deflection, and the alteration is in the same sense as that observed in the ordinary discharge tube. We have, then, learnt that the difference of deflection observed with varying gas pressures in the ordinary discharge tube is not caused by difference of the medium in which the deflection is observed, but in the difference of the rays themselves which are produced with varying pressures of gas.

§ 5. In order to further demonstrate the independence of the deflections from the medium in the observing space, we again keep the conditions of production of the rays constant, as before (§ 3), but replace the atmospheric air in the observing space on this occasion by hydrogen gas. At a pressure of 422mm. this gas becomes just clear enough for the experiment. The deflection is again equal to 10mm. (±0·5mm.), as in air. It remains also unaltered, if the pressure of hydrogen be lowered step by step down to 0·012mm. Twenty different intermediate pressures were investigated. Also in oxygen and in carbon dioxide the deflection was constant and equal to 10mm. with all the pressures used (3·3mm. to 0·034mm. for oxygen and 10mm. to 3mm. in carbon dioxide).

§ 6. The rays retain the same capacity for deflection all along their length. We test this by moving the diaphragm, magnet, and screen together further and further from the window, all the other conditions remaining the same, and measuring the amount of deflection at each step. This experiment was carried out in hydrogen gas at 37·5mm. pressure at distances of 5 and 10cm. between diaphragm and window; at 12mm. pressure at 5, 10, 15, 30cm. distance; lastly, at 1·5mm. pressure and distances of 5, 15, and 30cm. The deflection remained equal to 10mm. throughout,

† See *The Electrician*, Vol. XXXII., March 23rd, *et seq.*
‡ The arrangement is one of these described before, only the observing tube is shortened to 50cm.

Digitized by Google

§ 7. The above experiments showed that the amount of the deflection was also independent of the intensity of the rays. For this intensity was very varied in the different media traversed by the rays and at different distances from the window, judging not only from the previously determined transparency of the media, but also directly by the brilliance of the phosphorescent spot.

In order to especially test this independence, an aluminium screen was inserted in the observing space close against the window. This screen could be either placed in the path of the rays or removed from the same at will. In the former case, the rays coming from the window had to traverse another aluminium sheet 00·05mm. thick (twice the thickness of the window, 15 times that of aluminium foil), and this weakened their intensity to a marked degree; in the second case they remained unweakened

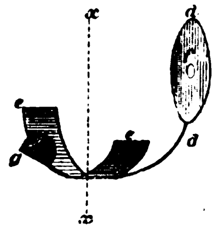

FIG 1A.

as formerly. The position of the deflected spot on the scale of the phosphorescent screen was now observed alternately with and without the intermediate aluminium screen without any displacement being observable. The experiment was conducted in air at 0·024mm. pressure, in hydrogen at 20mm. pressure, and in oxygen at 0·03mm. pressure. The arrangement of the aluminium screen used is shown (perspectively) in Fig. 1A, *e e* is a strip of sheet iron, *d* a wire soldered across it, both being bent according to the radius of curvature of the observing tube. The wire carries on one side the opaque sheet iron *d d*, with an opening *f* 1·7mm. in diameter, the same size as the window, and on the other side the balance weight *g*. The opening *f* is, on the back, covered with the sheet aluminium of the thickness described, and is at such a height that it lies exactly on the window when the screen is drawn against it

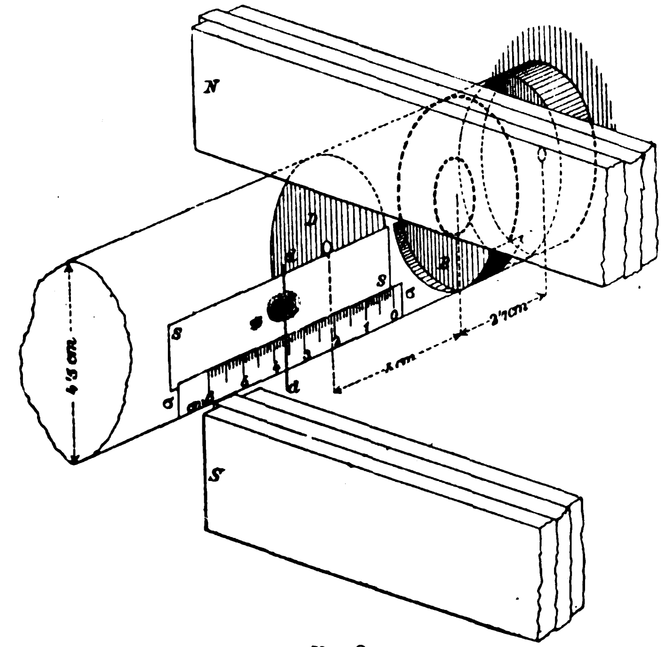

FIG. 2.

by the aid of a magnet. This is the position in which the screen finds itself in the path of the rays; if the path of the rays is again to be free, the screen is turned through 90deg. about the vertical axis *x x*. When this screen was in use the blind B (Fig. 1) was removed.

Thus the attempt to alter the deflection of the rays, that is, the amount of their curvature for a given magnetic field, by any alterations whatever in the observing space, was completely unsuccessful.

§ 8. The constancy of the deflections was still more rigorously tested than before in the following manner. The small magnet was replaced by a very powerful and large one, which was set up near the observing tube and took it between its poles (Fig. 2). The rays were now much more strongly curved than before; the spot would no longer fall on the screen used before, but on the glass wall. The screen, *s s*, used in this case, a strip of paper soaked in pentadecylparatolylketone, lies therefore on the inner wall of the tube, and there picks up the spot Φ. Parallel with the screen, but somewhat below it, is fixed the millimetre scale σ outside the tube, having its zero in the plane of the diaphragm. A vertical wire, *d d*, can be pushed along the scale forming a means of reading off the position of the phosphorescent spot on the scale. To avoid parallax, the eye is directed while getting the wire on the spot to a somewhat distant fixed point. This placing of the wire on the spot is done in the dark; only when it is completed is the scale illuminated in order to read the position of the wire on it. This method of working has the advantage over that used before, that it cannot be influenced in any way by prejudice.

In order to secure as far as possible constant conditions of production, the following plan was adopted:—Before each reading the pressure of gas was made somewhat too high in the discharge tube to allow the spark between the discharge knobs, placed 2 8cm. apart, to take place. If now the level of the mercury in the pump was lowered, the pressure in the discharge tube was gradually reduced, and the phosphorescent spot consequently moved (§ 4) to positions of less deflection (to greater numbers on the scale), generally moving about 8mm. During this movement the movable wire, *d d*, was gradually pushed after the spot, following it steadily, until such time as the sparks became audible, showing that the pressure in the tube had reached the predetermined desired value. The position of the wire thus obtained was read off as the required position of the phosphorescent spot on the scale. In this manner the following table was obtained in which every position is the mean of three separate readings.

Gas.	Pressure. mm.	Position of spot. mm.	Deviation from mean mm.
Air	31·0	33·9	+0·2
	15·4	33·5	-0·2
	6·4	33·3	-0·4
	3·5	33·7	0·0
	1·1	33·5	-0·2
	0·16	33·8	+0·1
	0·10	33·7	0·0
	0·022	33·6	-0·1
Hydrogen	332·0	33·1	-0·6
	220·0	33·4	-0·3
	149·0	34·1	+0·4
	108·0	33·9	+0·2
	50·5	33·6	-0·1
	23·8	34·1	+0·4
	4·3	33·8	+0·1
	0·48	33·6	-0·1
	0·020	33·8	+0·1

Mean of all positions, 33·67.

The constancy of the deflections for such varied pressures in two so different gases is thereby shown with the greatest certainty attainable by such measurements. The variations of the individual observations from the mean (last column) only in one case surpass ½mm., and this only with a high pressure, when the tenths of millimetres, only estimated in any case, become uncertain owing to the diffused nature of the spot. A relation between the alterations of gas or pressure, and those of the deflection, is not to be traced.

§ 9. Earlier researches showed that cathode rays which are produced at smaller degrees of vacuum, have more diffused paths than those which are produced at smaller pressures. Now, there appears (§ 4) yet another difference in these two kinds of rays; the former rays are more deflected by a magnet than the latter.

Just as the kind of rays here under investigation, namely, those produced at given pressure by a given apparatus, keep the amount of their capacity for deflection as an unalterable and characteristic distinctive quality, so would very probably also every other kind of ray produced by other apparatus at other pressures keep its particular capacity for deflection under all circumstances. If this be assumed, then a particular kind of cathode ray would be better characterised by its "deflectibility" than by a description of the circumstances of its production. We will also combine the two above results in this manner: the more "deflectible" cathode rays have more diffusion in gases than the less deflectible.

§ 10. It only remains to call attention to the peculiar deformations which were observed in the deflected phosphorescent spot.

The spots of undeflected rays were, as described before, always circular, and the distribution of light in them was dependent on the amount of turbidity of the gas in the observing space; in very turbid (dense) gases the edge of the spot is undefined; if the gas becomes clearer (rarer), there appears in the centre of the spot a more or less sharply-defined kernel, surrounded by a less bright penumbra; and whether gas is almost entirely removed from the observing space, the core alone remains, the penumbra has vanished.

Digitized by Google

Even after deflection the spots retained in general this appearance, depending on the amount of turbidity of the medium, but the following details are to be noted:—Firstly, the deflected spots are always elliptical, with the major axis of the ellipse in the direction of the deflection. This is, perhaps, to be at once explained by the fact that the pencil of rays no longer encounters the screen at right angles to its plane. In very turbid gases no deformation but this elliptical one was to be seen. For the measurement of the amount of the deflection the centre of the ellipse was always used. But if the gas became more transparent, so that the spot had core and penumbra, the appearance of the spot was subjected to intermittent sudden changes from discharge to discharge. Fig. 3 (No. 1—5) show certain typical forms occurring in this case. The left-hand picture gives in every case the (unalterable) shape of the undeflected spot, the one on the right one of the (changing) shapes of the deflected spot; the deflection is thus imagined as directed from left to right. The part remaining constant during these changes was the position and shape of the deflected core; the centre of the core was, therefore, utilised for the measurement of the amount of deflection. The position and shape of the penumbra are alone subject to change. Often enough the penumbra remained after deflection concentric with the core (No. 1); not infrequently, however, it was displaced excentrically (Nos. 2, 3, 5), often so far that it appeared completely separated from the core (No. 4). The displacement of the penumbra was always in the direction of further deflection; in no

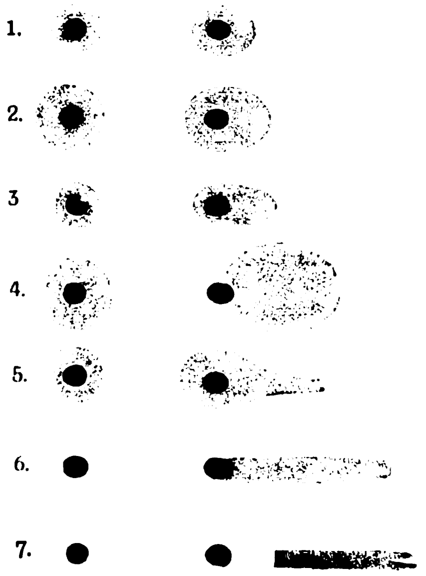

FIG. 3.

case was the penumbra less deflected than the core. Plainly, then, the penumbra often contains rays of greater deflectibility than the core, but never rays of less deflectibility. This is just what is to be expected if, besides the great mass of rays, composing the core, whose capacity for deflection does not alter from discharge to discharge, there are produced a certain number of other rays, varying from discharge to discharge, of variable, but never less deflectibility. These latter rays must then be found in the penumbra, for more deflectible rays have more diffused paths in gases than less deflectible ones.

If the gas pressure in the observing space be very small, such separation of the rays of different deflectibility by diffusion can no longer be produced. This separation is then produced by the magnet only. In this manner phenomena such as those shown in Fig. 3, Nos. 6 and 7, are produced, and which might be called the magnetic spectra of the cathode rays. As in the optical spectrum of rays of light of different refrangibility, the cathode rays of different deflectibility are here found separated in space from one another.

§ 11. The deflection of the cathode rays is, according to Hertz's experiments, not an action of the magnet on the rays themselves, but an action of the magnet on the medium traversed by the rays; the rays spread themselves differently in a magnetised and in an unmagnetised medium. For if forces worked between the magnet and the rays themselves, then the magnet itself, if made movable, would be deflected by the rays, which is not the case.* But the medium, whose magnetic alteration is shown by the curvature of the rays, is according to our experiments, the ether itself. For the curvature was found to be completely independent of the nature and density of any ponderable medium which chanced to be present, and was especially to be seen in the highest obtainable vacuum.

* Hertz, *Wied. Ann.*, 19, pp. 799 and 805; 1883.

Cathode rays give, therefore, by their curvature, distinct evidences that the condition of the ether between magnet poles is really altered, as is demanded by the theory of the action at a distance produced by them. The magnetic rotation of the plane of polarisation of light does not give any such evidence; for it only occurs through the mediation of matter, it differs from medium to medium, and does not occur in airless space.

A METHOD FOR THE TREATMENT OF ROTATING OR ALTERNATING VECTORS, WITH AN APPLICATION TO ALTERNATE CURRENT MOTORS.

BY PROF. GALILEO FERRARIS.

The study of certain modern electro-technical apparatus, and notably that of any kind of electric motors, leads to the consideration of alternating vectorial magnitudes. For the treatment of such magnitudes it may help to have recourse to some mode of graphic representation, which may give in itself, not only the amplitude and the phase, but also the direction.

I here present a simple and obvious method which may assist in the interpretation and in the elementary explanation of many phenomena. In order to show, therefore, the usage and utility of the new method, I apply it to magnetic fields, and explain by means of it an elementary theory of the principles of electric motors with alternating currents.

PART I.—ROTATING VECTORS AND ALTERNATING VECTORS.

1. *Definition.*—I shall designate by *rotating vector* a vectorial magnitude of which the scalar value is constant, whilst the direction rotates about an axis with uniform velocity. We shall here limit ourselves to consider rotating vectors in a given plane. In this case, to define a rotating vector, the following elements are necessary to us:—The *magnitude*, the *sense*, the *frequency*, or number of turns made in a unit of time, and the *phase*, or fraction of a turn reckoned from the origin of time. Given the frequency, we can represent the rotating vector by means of a segment of a straight line, od or os (Fig. 1), making simply this assumption,

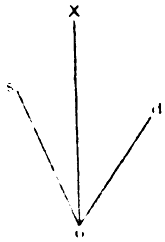

FIG. 1.

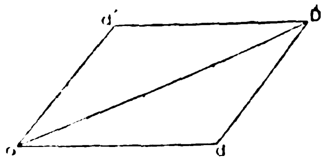

FIG. 2.

that the length of the segment represents the magnitude of the vector, that the direction of the same may be that which the vector has at the origin of time, and that the letters d or s indicate the sense *right* or *left* of the rotation. If oX is the straight line from which it is wished to measure the angles described by the vector, the angle Xod or Xos is that passed through by the vector from the origin of time, and is called the angular value of the phase. The ratio $\frac{Xod}{2\pi}$, or $\frac{Xos}{2\pi}$, is the phase. To name the vectors thus represented we shall make use simply of the letters d and s.

2. *Composition of Two Vectors of equal frequency rotating in the same Plane. First Case.*—Vectors rotating in the same sense.—Take two vectors rotating in the same sense and with the same frequency, and let them be, for example, d and d' (Fig. 2). At any moment their vectorial sum or their resultant is the vector represented by the diagonal o D of the parallelogram made upon them, or that which is equivalent to it, by the straight line o D, which closes the triangle od D or the triangle od' D. Now, if d and d' rotate in the same sense and with the same angular velocity, the angle dod' remains constant. The diagonal o D therefore also remains constant. It meanwhile rotates about o with the same angular velocity as the components. Thence the resultant of two vectors of equal frequency rotating in the same plane and in the same sense is also a vector rotating in the same sense and with the same frequency. If the angle dod' is equal to two right angles, if also the phases of d and of d' differ by 180deg., we say that d and d' have opposite phases. If the two component vectors have equal magnitudes and opposite phases, their resultant is zero.

It is unnecessary to say how from the case of two vectors only you pass to the case of any number of vectors rotating in the same plane and in the same sense; and as it was shown that the re-

Digitized by Google

sultant vector is also a vector rotating in the same plane and in the same sense, and is represented by the straight line which closes the polygon made by the component vectors.

Second Case.—Rotating vectors in opposite senses.—If the two component vectors (Fig. 3) *o d*, *o s*, rotate in opposite senses, the angle *s o d* varies; then the diagonal *o* A inevitably varies in magnitude. It also may vary, and in general does vary in direction.

But we have to consider two cases: (*a*) The case in which the magnitudes *o d* and *o s* of the two component vectors are equal to each other; (*b*) that in which those magnitudes are unequal.

3 (*a*). *Case in which the Two Component Vectors have Equal Magnitudes.*—In this case the resultant has a fixed direction. In fact the diagonal *o* A is then at any moment the bisectrix of the angle *s o d*, and thus *o d* and *o s* rotate with the same angular velocity, one towards the right and the other towards the left. Thus it remains fixed in space. Instead, the *value* of the resultant varies, being bound to the variable angle A *o d* in the relation

$$o\,\text{A} = 2\,o\,d \cos \widehat{\text{A}\,o\,d}.$$

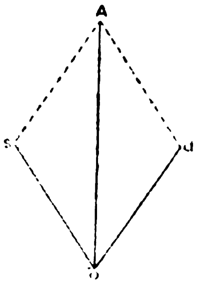

Fig. 3.

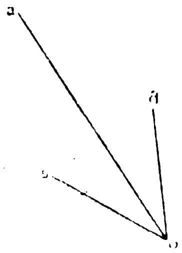

Fig. 4.

Supposing *o* A $= a$ and $2\,o\,d = \text{A}$, representing by *n* the frequency by *t* the time, and by *α* the value of the angle A *o d* when $t = o$, this relation can be written thus:

$$a = \text{A} \cos (2\,\pi\,n\,t + \alpha).$$

A magnitude varying according to this law is that which one commonly calls an *alternate*, or *alternating harmonic*, or *sinusoidal* magnitude. The constant A is the *amplitude*, *n* the *frequency*, the angle *α* the *angular value of the phase*, when you take as the origin of time the instant in which *a* is at the maximum. We, therefore, call *o* A an alternating vector, and conclude:—Two equal vectors rotating in the same plane with the same frequency, and in opposite senses give for resultant a vector of fixed direction, alternating with the same frequency. The direction of this alternating vector is that of the bisectrix of the angle which at any moment is contained between the two component vectors, is, therefore, also that of the bisectrix of the angle which the two component vectors contain in the instant in which $t = 0$, or that of the two segments of straight lines by which are represented, according to our assumption, the two component vectors.

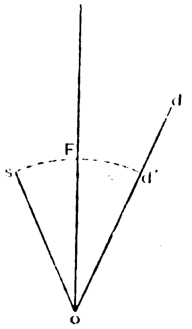

Fig. 5.

The amplitude of the resulting alternating vector is equal to twice the magnitude of one of the component vectors. *Vice versâ*, a sinusoidal alternating vector may always be decomposed into two rotating vectors of equal value and of opposite direction. Any sinusoidal alternating vector may be considered as resulting from two rotating vectors in the same manner. Now this mode of considering an alternating vector leads to very simple graphic representations, in order to indicate by an alternating vector the fixed direction, the amplitude, and the phase. The artifice consists in representing by a segment of a straight line the direction and the amplitude of the alternating vector, and ,with other segments of straight lines the rotating vectors of which this is compounded. Drawing all these three segments we have the figure indicated in Fig. 4. In this figure the segment *o a* indicates the direction and gives the amplitude of the alternating vector, whilst the segments *o d* and *o s* represent the rotating vectors, right and left into which *o a* may be decomposed. The angle *a o d*, or its equal *a o s*, represents the angular value of the phase. But as $o\,a = 2\,o\,s = 2\,o\,d$, and is only the bisectrix of the angle *s o d*, any one of these segments *o a*, *o s*, *o d* may be found when the other two are given. Whence we have a complete representation by merely drawing these two. By this method we can represent the alternating vector simply by *o a d*, or by *o a s*, or by *o s d*.

4 (*b*). *Case in which the Two Component Vectors have Different Magnitudes.*—If the component rotating vectors *o d* and *o s* (Fig. 5) are

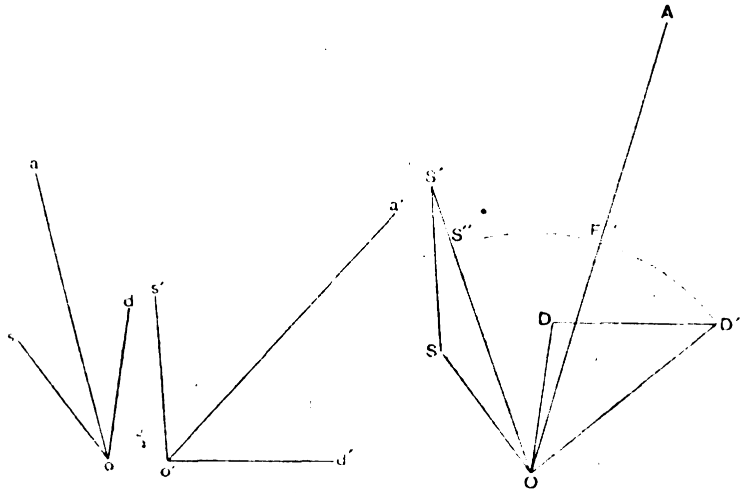

Fig. 6.

not equal, not only is the amplitude variable, but also the direction of the resultant vector. With the centre *o*, and with a radius equal to the smaller of the component vectors, equal to *o s* in the case of this figure, describe the arc of the circle *s* F *d'*. We may consider *o d* as the resultant of the two vectors *o d'* and *d'd* rotating in the same sense. Now, the two rotating vectors *o d'* and *o s* givefor resultantan alternating vector *o a* of fixed directionbisectrix of the angle *s o d*, and of amplitude $o\,a = 2\;o\,d' = 2\;o\,s$. Thence the

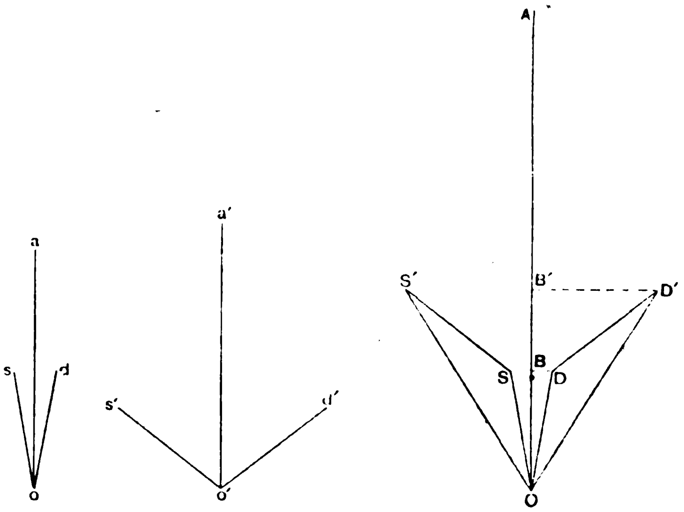

Fig. 7.

two rotating vectors *o d* and *o s* of opposite phases, and of different values, are equivalent to an alternating vector *o a* of fixed direction and to a rotating vector *d' d*.

5. *Composition of Two or More Alternating Vectors of Fixed Direction.*—Making use of the preceding considerations, we may reduce the composition of alternating vectors to that of rotating vectors. If, for example, we have two alternating vectors of fixed direction *o a s d* and *o' a' s' d'* (Fig. 6) we can compound *d* with *d'* and *s* with *s'*, and then compose together, in the manner before indicated, the two resultants. To compound *d* with *d'* we draw from a point O a segment O D, equal and parallel to *d*, and from D a segment D D' equal and parallel to *d'*; we thus find the resultant O D'. To compound in the same way *s* with *s'* we draw O S and S S' respectively equal and parallel to *s* and *s'*, and draw O S'. After that we can say whether the system of the two given alternating vectors *a* and *a'* is equivalent to the system of the two rotating vectors O D' and O S'. Now, having two rotating vectors O D' and O S', we can apply the preceding construction. If O D' is the lesser of the two, we take O S'' = O D', and on the bisectrix O F of the angle S' O D' we take O A = 2 O D' = 2 O S''. The two rotating

Digitized by Google

vectors O D′ and O S′, and whence also the two given alternating vectors a and a' are equivalent to the alternating vector O A and to the rotating vector S″ S′.

The proposition can be extended without doubt to the case of any number of alternating vectors; whatever system of alternating vectors of equal frequency situated in the same plane, can be reduced to a simple system of an alternating fixed vector combined with a rotating vector. The manner of doing this is again that indicated in Fig. 6 with this sole difference, that in place of the triangles O D D′, O S S′ we have to make the polygons of all the components d and of all the components s of the given vectors. It is of importance to apply the proposition to particular cases.

6. *Particular Cases: (a) Alternating Vectors having the same Direction.*—Ia' is parallel to a (Fig. 7) the angles O S S′, O D D′ are equal to one another, whence the triangles O S S′, O D D′ are equal, and in consequence O S′ = O D′. Besides the bisectrix O A of the angle, S′ O D′, is also bisectrix of the angles S O D and S′ S, D D′, and is also parallel to $o\,a$ and $o'\,a'$. Thence the resultant O A, of the two alternating parallel vectors a and a', is also an alternating fixed vector, and is parallel to the components. In order to find this resultant it is not necessary to make use of all the construction indicated in Fig. 7. It is evidently sufficient to make a moiety of it; for example, the part O D D′.

According to the interpretation before given to the figure, the segments O D and D D′ represent the half of the component alternating vectors, and the segment O D′ represents the half of the magnitude of the resulting alternating vector. If we let fall the perpendiculars D B, D′ B on O A the *projections* O B, B B′ and O B′ represent similarly the half of the instantaneous value which the two component vectors and the resultant have at time $t=O$; and if it is supposed that the figure O D D′ revolves about O with frequency, n, the projections of O D, D D′, O D′ on the fixed line O A represent at any moment the half of the instantaneous value of the same vectors. But we can now represent with O D and with D D′ not the half but the entire amplitude of the component vectors, and with that we have at once in O D′ the representation of the magnitude of the resultant, and in the projections on O A the representations of the instantaneous values of the magnitudes of the three vectors under consideration. Thus we found the known and only construction, of which we make use, in the study of alternating magnitudes. This is a particular case of the more general construction indicated by us.

The facts considered extend, without doubt, to the case of any number of parallel alternating vectors.

(To be continued.)

ELECTRIC TRANSMISSION OF POWER FROM THE PERIYAR RIVER, SOUTHERN INDIA.*

A Committee, consisting of Colonel J. Pennycuick, R.E., Secretary to the Government of Madras P.W.D., Professor Unwin, Professor George Forbes, and Professor W. C. Roberts-Austen, having been appointed to consider the whole question of the use of the water power available on the Periyar Irrigation Works, have now issued the report of three of their number, and separate reports as notes by each member of the Committee. On the eve of his departure, last July, for America, Professor Unwin withdrew from the deliberations of the Committee, but his note is a very important one. Irrigation works are now in progress upon the Periyar River in the Madras Presidency, and when completed there will be a large amount of water-power available. The subject may be divided into two branches—firstly, the development of the power at the site by suitable hydraulic works; and secondly, its utilisation upon the spot or transmission to distant places. A note supplementary to Prof. Unwin's was added by Col. Pennycuick upon the hydraulic plant. It appears from the report that the development of power at the site would not cost more than £4 per horse-power for the hydraulic apparatus alone, and that the electrical apparatus for its transmission to Madras would not cost more than £35 per horse-power delivered at that city, while for the towns of Madura and Trichinopoly the cost would not exceed £23 and £17 respectively, the most important item being that of the conductors, which depends directly upon distance. After making due allowance for interest on first cost and depreciation of plant, it appears that power can be delivered in the three towns named at an annual cost per horse-power of £3, £2, and £1. 10s. respectively. Comparing these figures with the cost of steam power, there would seem to be every probability that a large portion of the available power can be profitably used in the towns in question as well as in the smaller towns on the road thereto. The most obvious and probably the most profitable use of power would be for electric lighting in the towns. It appears that none of these towns are supplied with gas, and that in Madras the cost of lighting by oil lamps forms a considerable portion of the municipal expenditure. The Committee concur in the view of the chief engineer to the Government of Madras, that the water should be brought to the hydraulic motors by means of pipes, a separate pipe being used for each motor, or, at most, two motors being fed from one pipe, and that, with a view of reducing lost, the fall should be divided into two or three stages. The great cost of a channel in the rock to carry all the water appears prohibitive.

The note by Col. Pennycuick, R.E., on the hydraulic apparatus required, states that the side slopes of the valley are such that there would be no difficulty in laying the pipes with a slope of 2¼ or 3 horizontal to 1 vertical, and the length of the pipes may be taken at three times the head. The total fall is a little over 1,000ft.; a single pipe for the full head would therefore need to be very thick at the base to withstand the pressure, and he therefore advises that the fall should be divided into two parts. Each stage would thus have 500ft. head, and each pipe would be 1,500ft. long. He recommends that the velocity of discharge shall not exceed 10ft. per second, and with a pipe 3ft. diameter, the effective head for each pipe would be 485ft., and it would develop 2,829 H.P. In Prof. Forbes' report on the electrical transmission of power the unit is taken at 5,000 H.P., and to generate this power on a fall of 500ft., about 120 cubic ft. of water per second would be required, and this would be carried by a pipe 4ft. in diameter with a velocity of between 9ft. and 10ft. per second. The pipe would have a mean thickness of ⅝in., and would weigh 392lb. to the foot. The total weight would be 262·5 tons, and the cost at £20 per ton £5,250, to which must be added £2,500 for cost of carriage to the site and £600 for laying, making the total cost £8,350. A turbine to generate 5,000 H.P. would cost about £6,000, and £750 might be added as a share of general expenses. The total cost of the plant would be £15,000, or £3 per horse-power. For a pipe 2ft. diameter, which would develop 1,230 H.P. the cost works out to £2,500, and inclusive of turbine about £3·67 per horse-power. Whatever units are employed the capital cost per horse-power would not exceed £4, and the annual charge 10s. per horse-power. The author had previously suggested Pelton wheels, but the Committee pointed out their impracticability for this special purpose.

A preliminary memorandum by Prof. Unwin is added in which he says that from the data supplied to him he finds there is a supply of 600 cubic feet of water per second all the year round, and a fall of 1,200ft.; this would yield 60,000 effective horse-power. He advises that that the fall should be divided into two parts, and as steel pipes of 4ft. and 5ft. diameter have been used in America, he considers that a steel pipe 4ft. diameter, double riveted for the lower part, and transverse joints riveted up from end to end, would be suitable. Such a pipe would carry 3,600 H.P. on 600ft. falls, and would weigh about 280 tons. The pipe might supply two turbines of 1,800 H.P. each. He puts down the capital cost for canals, pipes, turbines, and necessary buildings at from £5 to £10 per horse-power utilised. That power can be obtained cheaply is evident, if any application can be found for it. The hydraulic part of the problem is the least doubtful and the least difficult, and the cost of the power would be but a small fraction of the cost of electric machinery and transmission for applying it.

The next report is by Professor George Forbes, F.R.S., and deals with the electrical part of the problem. The author points out that he has no data as to cost of carriage, nor as to the cost of erecting a pole line to carry the conductors. He is, therefore, unable to give the cost of the work approximately. He proposes to develop the total horse-power of the fall by means of turbines, each of which would be capable of developing 5,000 H.P., and points out that if smaller units were used the cost would be greater. The dynamos would be fixed above the turbines upon vertical shafts. The points to which it is proposed to transmit the electricity are from 80 to 350 miles distant from the water power, and it is possible that a cheap power supply might attract factories to sites about 100 miles distant from the irrigation works. Besides the obvious field for supplying electricity for lighting purposes, the author suggests its use also for electric traction, and points out that the question is well worth consideration, whether the railways in the Presidency south of the town of Madras might not advantageously be worked by means of electric locomotives. He thinks that in India, where the atmospheric conditions are so favourable, it would be safe to contemplate the use of 30,000 to 40,000 volts. Passing to the current, he alludes to the fact that hitherto it has been impossible to construct a continuous-current dynamo of high electric pressure successfully, this arising from the fact of a commutator being necessary. An alternating-current dynamo can also be obtained about 40 per cent. cheaper than a direct-current machine for the same capacity when dealing with large amounts of power.

Dealing next with the question of phase, he points out that the single-phase is admirably adapted for all lighting purposes, and

* Abstract from the *Engineer*.

Digitized by Google

that synchronising motors work with a very high efficiency, but they require to be started mechanically. Two-phase and three-phase motors start perfectly well on full load, and they have no commutators. The disadvantage of the multi-phase motors is that they require more than two wires, which is a defect. When alternating currents are used for transmission it is probable that the best way of using the power for traction purposes is to convert the alternating into a continuous current at the place where it is used by means of an alternating-current motor driving a continuous-current generator. The author states that certain advantages have been claimed for the three phases, that the cost of copper in the conductors is less than with two phases, and that the turning power given to a motor is more uniform with three phases than with two. But these claims are untenable. He puts aside the three-phase system as unsuitable, and gives reasons for preferring the two-phase system. With regard to frequency for motive-power purposes, he prefers about 10 periods per second, but if the current is to be used for electric lighting, such a low frequency is not available.

In the present case it is probable that a large amount of current would be used for the lighting of Madras, and therefore he would prefer, on the whole, to use a frequency of 50 periods per second, although the efficiency of the motors would not be so high as a frequency of 10 periods, and might only amount to 85 per cent. He dismisses the question of using step-up and step-down transformers as adding largely to the cost, and finally proposes to use a type of machine with the following characteristics :—5,000 H.P. vertical shaft generating 30,000 or 40,000 volts direct ; frequency, 50 per second, two phases ; the cost of such a dynamo may be taken at not over £6,000. The cost of transformers of 1,000 H.P. or over may be taken as certainly not over £1 per horse-power, and that they would probably not cost above half this amount. The principal cost would be for the line, which is next alluded to. The author proposes to use one overhead line for each 5,000-H.P. unit. The poles would be of A shape, and provided with special insulators, of which details would be furnished later on by the author. By this method it would be possible to use 40,000 volts, and transmit power 350 miles to Madras. With regard to density of current, this must be selected so that by either a slight increase or decrease in this density the additional gains and losses owing to difference in power wasted, and in interest on capital sunk, shall be equal. The author then gives a table showing for different densities of current the cost of copper in the line. With a density of 100 amperes per square inch the cost of copper per horse-power generated would be £70, and per horse-power delivered £76. At this rate 92 per cent. of the power produced would be delivered to Madras. With a density of 500 amperes per square inch the figures would be £14, £23, and 68 per cent. respectively ; and with a density of 1,000 amperes per square inch would be £7, £35, and 20 per cent. The cost of poles and insulators for each unit of 5000 H.P. may be taken at £90 per mile, being £1 per pole, and 2s. 6d. per insulator and attachments, and sixty poles to the mile. Assuming a density of 400 amperes per square inch, the total cost of the principal parts of the electrical plant come out as follows :—

Copper on the line	£25·0
Poles and insulators	6·3
Dynamos for 1·46 H.P.	1·75
Transformer for 1 H.P.	1·0
Per horse-power delivered total	£34·05

The annual charge may be taken at £1·91. The author has dealt with the case of Madras as being the crucial question, as if the power can be supplied to that city it can, of course, be supplied to points which are nearer the generating plant. He says that it seems quite clear that it will be possible to supply electricity at any low pressure suitable for electric lighting or motive-power, at not more than £4 per annum, including all costs, with a margin for contingencies.

ON THE TRANSFORMATION OF OPTICAL WAVE-SURFACES BY HOMOGENEOUS STRAIN.*

BY OLIVER HEAVISIDE, F.R.S.

In the optical wave-surface invented or discovered by Fresnel only one kind of eolotropy is concerned. But it may be either elastic eolotropy or inertial eolotropy, according to the particular theory employed. In the electromagnetic theory it may be either electric or magnetic eolotropy. In real fact it is the former, but it might be either. If there be duplex eolotropy, both electric and magnetic, the optical wave-surface is of a more general type, including Fresnel's, at its two extremes. It has some theoretical attractions on account of its symmetry with respect to the two eolotropies, whereas the Fresnel surface shows but an imperfect development of the theory concerned. Dr. Larmor has recently made the interesting remark that a duplex wave-surface of a special type, viz., with homologous eolotropies concerned, may be homogeneously strained to a simplex (or Fresnel) wave-surface. I have examined this question more generally, with these main results :—Any duplex wave-surface, when subjected to any homogeneous strain, usually remains a duplex wave-surface ; but sometimes it degenerates to a simplex wave-surface. There are four principal cases. When the strainer varies as the square root of the permittivity, and when it varies as the square root of the inductivity, we have the two simplest cases. But each of the reduced simplex surfaces may be strained to its reciprocal, also a simplex surface. This makes four. These transformations lead to a more interesting one, viz., that the duplex wave-surface itself may be strained to its reciprocal (of the same type) by a pure strain. This strain may also be replaced by three pure strains in succession, viz., first, turning the duplex to a simplex surface ; secondly, inverting the latter ; and thirdly, straining it to become the reciprocal of the original. There are two sets of such triple strains.

* Abstract of a Paper read before the Royal Society.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 11, 1894.

Ocean Telephony.—Prof. M. I. Pupin, of Columbia College, has been granted patents for a method which, it is claimed, renders practicable ocean telephony and the use of Hughes' apparatus, for instance, for cable telegraphy. One patent relates to the principle, which consists in the employment in series of condensers interposed between the parts of a cable divided into lengths, the number of parts depending on the periodicity of the current to be transmitted. The patent gives the following statement of the new invention :—"Consider the current in the conductor of any section of the cable. That current consists of two distinct parts. One part is due to the charging of the terminal condensers of that section, and the other is due to the charging of the surface of the conductor itself. The first current I call the longitudinal displacement component, and the second current I call the lateral displacement component of the current in that section. The above-mentioned very important improvement consists, therefore, in diminishing the ratio between the lateral and the longitudinal displacement components of a rapidly varying current. The wasting of a current due to the lateral displacement components in the various parts of a cable acts evidently like an impedance, therefore it is to be understood that the word 'impedance' herein includes the impedance due, not only to ohmic resistance, self-induction, &c., but also the impedance resulting from the lateral displacement currents." In order to prevent discontinuity of the cable through a condenser breaking down, an induction coil is placed in shunt with each condenser, the coil being so constructed that the effect of the condenser capacity upon the current through the coil will be inappreciably small, with frequencies over 50 periods per second. The introduction of the impedance of this coal in the main circuit in case of a fault in the circuit will also permit the fault to be located. Another patent relates to the construction of a transformer, and to the combination of such a transformer with a line conductor having in circuit telephone or telegraph instruments, or both, the secondary of the transformer being divided into a number of equal parts and condensers interposed between each of these parts. A patent on the construction of the line conductor is referred to in one of the patents as now pending.

An Electric Conduit Railway for New York.—The Metropolitan Traction Company of New York City, has announced that it has accepted the offer of the Siemens-Halske Company to construct three miles of an electric conduit road in the upper part of the city similar to that now in use at Budapest. The road is to be constructed at the expense of the Siemens-Halske Company, and, if it proves satisfactory, the contract provides for four additional miles.

Electric Traction in Cuba.—Arrangements have, it is stated, been made by an English company for the establishment of a system of electric tramways in Havana. The projected line covers about 20 miles in all, and is to connect the principal wharves and thoroughfares with the existing tramways.

CORRESPONDENCE.

WIRING PRICES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I notice in your issue of the 18th inst. a letter from a professional gentleman in Manchester complaining of my having made remarks at Winchester, which he construes into an advocacy of jerry work in electrical wiring. It appears that the said member of the profession, as distinguished from the electrical plumbing fraternity, bases his views on his opinion that the work could not be well done at the price named; but in this he is mistaken. My suggested price of 8s. 9d. per light was confined (by an explanation, unfortunately not reported) to the ordinary cases of shop wiring, in which there would be, say, five lights on one line in the window and five lights on another line over the counter, with one switch for the window lights and two switches for the counter lights. Your correspondent has probably not realised how extremely simple such cases are, and how easily they lend themselves to economic treatment.

Time was when it was considered the function of a professional engineer to secure the maximum result for the minimum expenditure, but I regret to say that during the past few years the perusal of professional specifications has led me to the belief that in many cases the object aimed at was the exact reverse. I should have thought, however, that your correspondent would have been more careful not to have allowed the impression to get abroad that his practice was of a similar nature.

As to the case in point, I have made a careful estimate of the exact cost of materials and labour involved, and find that the whole can be supplied and properly fitted up at the price named, in accordance with the Phoenix Fire Office rules, at a fair profit to the local electrical plumber, but I will concede this much to your professional correspondent that I think on mature reflection an important job of this kind should not be undertaken without professional assistance, and on this account my suggested price might very well be raised to the extent of one shilling, thus providing a half-guinea fee to the professional man. I think perhaps your correspondent has not fully realised that in speaking at Winchester I had a clear view of the fact that there is no prospect of any work being undertaken there for at least 12 months to come, and that taking into consideration the spread of education, we may suppose that during that time electrical plumbers will succeeded in mastering the elements of arithmetic necessary for solving the problem—"if a herring and a-half cost three half pence, what will a dozen cost?"—without the aid of a professor.—Yours, &c., John S. Raworth.

Albert Buildings, 49, Queen Victoria-street, London, E.C., May 22, 1894.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

The 1894 Edition of "The Electrician" Electrical Trades' Directory and Handbook is now ready. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"Electric Lamps and Electric Lighting," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"Electrical Engineering Formulæ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"Electromagnetic Theory," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"Inventions, Researches and Writings of Nikola Tesla," by T. Commerford Martin, may be obtained from the Publisher of *The Electrician*, and a copy will be forwarded post free on receipt of 16s. 6d.

"How to Wire Buildings."—Copies of this work, by Augustus Noll, will also be sent by the Publisher post free on receipt of 6s.

Tenders Invited.—The Corporation of Bedford invite tenders for the construction, supply, and laying down of the necessary plant and mains for the supply of electric current within the borough. The contract is in two sections, of which particulars are given in our advertisement columns. Specifications can be had at the offices of Mr. F. H. Medhurst, B.Sc., 13, Victoria-street, Westminster, S.W.; and tenders must be sent in to Mr. T. S. Porter, clerk to the Urban Sanitary Authority, the Town Hall, Bedford, not later than Saturday, June 16th.

——— The Guardians of the Parish of Paddington (London) invite tenders for the electric light wiring and fittings for the infirmary situate in Harrow-road, W. Further information can be obtained of Mr. A. W. Sclater, 182, Oxford-street, W.; and tenders must be sent in to the offices, 289, Harrow-road, W., before five o'clock on Tuesday, June 12th. Mr. H. F. Aveling is clerk to the Guardians. Some further particulars will be found in our advertisement columns.

Tenders Accepted.—The tender of Messrs. Walker and Co., of Queen-street, Portsea, has been accepted by the Portsea Board of Guardians for providing and fixing electric light fittings, &c., in St. Michael's-road, at £67. Tenders were also received from two other local firms, at £79. 17s. 6d. and £119 respectively.

——— The following is the full list of the tenders received recently by the Corporation of Brighton:—

For Motor Alternators.

	£	s.	d.
John Fowler and Co.	£5,147	0	0
Manchester Edison-Swan Company	3,940	0	0
Siemens Bros. and Co.	2,560	0	0
Brush Electrical Engineering Company	2,450	0	0
Easton, Anderson and Goolden	2,125	0	0
Crompton and Co.	2,110	0	0
*Electrical Construction Company	1,731	17	0

Tenders for Alternating Current Cables.

	£	s.	d.
Siemens Bros. and Co.	£4,745	3	4
Fowler Waring Cables Company	3,960	18	4
*British Insulated Wire Company	3,579	6	0

* Accepted tenders.

——— The Huddersfield County Council have accepted the tender of Messrs. Calvert and Co., of Folly Hall, for the supply of an air vessel for the electric lighting works.

Liquidations.—At meetings of the shareholders of Swan's Electric Light Company (Limited), (?) held on April 21st and May 12th, at 141, Pilgrim-street, Newcastle-upon-Tyne, it was resolved that the Company be voluntarily wound up, and Mr. T. R. Hutchinson was appointed liquidator.

——— The shareholders of Wells, Gallimore and Taylor (Limited), at a meeting held on the 12th inst., resolved that the Company be voluntarily wound up, Mr. E. M. Sharp, chartered accountant, of Birmingham, being appointed liquidator.

Appointment.—Capt. W. P. Brett, R.E., has been appointed an instructor in electricity at the Royal Military Academy.

Digitized by Google

VACANT APPOINTMENTS.—The Commissioners of Sewers of the City of London invite applications for the post of Inspector under the Electric Lighting Acts. Particulars of the duties required of applicants can be had on application to the City Sewers, Office, Guildhall. Further particulars are given in our advertisement columns, and applications must be sent in not later than noon on Tuesday, June 12th.

——— An advertiser requires the services of a practical working electrician to take charge of an installation of about 2,000 incandescent and 50 arc lamps. Applications should be sent in to No. 20B, *The Electrician* Office.

——— The Corporation of Cheltenham require in the Borough Engineer's Department an electrical engineer to superintend the laying of mains, and, subsequently, to take charge of the central station, at a salary of £200 per annum. Further particulars are given in our advertisement columns, and applications must be addressed to the Chairman of the Electric Lighting Committee, and sent in to Mr. E. T. Brydges, Town Clerk, not later than June 18th.

——— A leading firm of cable makers require a representative for Manchester and district. See advertisement elsewhere.

PERSONAL.—In our last issue it was announced that Mr. Arthur Ellis had been appointed clerk of the electricity works at Southport. Mr. Ellis has how been made resident electrical engineer, still retaining his position as clerk of the works during construction, Mr. Ellis was engineer to the Cambridge Electric Supply Company for nearly two years.

ALTERATION OF ADDRESS.—During the rebuilding of 11, Lombard-street, the temporary offices of the Guardian Fire and Life Assurance Company are situated at 6, Princes-street, Bank, E.C.

QUEEN'S BIRTHDAY.—The Foreign Office is to be lighted throughout by electricity on the occasion of the official celebration of the Queen's birthday to-morrow (Saturday).

NEWSPAPER INDEX.—Mr. Edward Curtice, who is well known in connection with the Press Cutting Agency, has just issued an index to *The Times*, the London morning and evening papers, and a number of weekly and provincial journals. The index claims to contain a record of the principal articles, correspondence reports, paragraphs, &c., appearing in the principal British journals; and the volume now issued covers the period from July 1st to September 30, 1893.

ADMIRALTY CONTRACT.—Messrs. Wiggins and Sons have again obtained the contract for the supply of mica to the Admiralty. This is, we understand, the largest order ever placed by the Department for this material.

AYR.—At a meeting of the Town Council a letter was read from the Caledonian Electric Supply Company, asking whether terms could be come to in the matter of lighting the district. The Company offered to take a transfer or lease of the Provisional Order on the understanding that ratepayers had the first chance of becoming shareholders of the Company to the extent of the capital necessary for completing the works. A long discussion ensued, during which several proposals were made, and ultimately a vote was taken on a motion that the Caledonian Company be allowed to approach the Council with a view to coming to terms, and this was agreed to by 9 votes, against 7 for a motion that a plebiscite be taken in order to ascertain the views of the ratepayers on the subject. During the discussion Mr. Auld, a member of the Lighting Committee, stated that he had already taken the opinion of the ratepayers for the ward he represented, and 75 per cent. of these were in favour of the introduction of the electric light.

ABERDEEN.—The question of lighting the new police buildings by electricity has been adjourned for a fortnight.

BALLARAT (AUSTRALIA).—It is announced that the Electric Light Co. have arranged for the erection of a preliminary plant for the lighting of a portion of the main thoroughfares of the municipality. It is anticipated that by the end of July a lighting plant costing about £40,000 will be imported from England. The machinery, &c., it is said, is to be erected under the supervision of Mr. K. H. Buchanan, C.E., Manager of the Crompton Electric Supply Company of Australia. The yards and grounds of the Ballarat Railway Station are also shortly to be lighted electrically; the number of fatal and serious accidents which have recently taken place in the shunting yards calling for an early adoption of the light, which will, it is expected, also be installed throughout the Government Offices at an early date.

BATTERSEA.—At the next meeting of the Vestry the following notice of motion is to be discussed:—"That considering the great expense of the horses of this Vestry, the Vestry is of opinion that electric motors be used in place of horses"!

BELFAST.—The Electric Lighting Committee of the Corporation have presented their report, in which the resident engineer sets out the progress made with the electric lighting works, and the Committee submitted Prof. Kennedy's plans and specifications for the central station in Chapel-lane, tenders for the building of which are now invited.

BLACKBURN.—It has been decided to light the new portion of the Free Library Museum by electricity, and the contract has been let to Mr. J. M'Lellan.

BOURNEMOUTH.—The Corporation have obtained from the Board of Trade an Electric Lighting Licence, and have instructed the surveyor to report upon the power at his disposal for electric lighting purposes. The Bournemouth Electric Supply Company have given notice of their intention to supply electric current continuously in certain streets of the borough.

CARLOW.—It is stated that the price paid by Major Alexander for the lighting plant, machinery, and goodwill of the Carlow Electric Lighting Company was £3,500, the original cost having been £20,000.

CHAPEL LIGHTING.—The Victoria-street Chapel, Blackpool, is to be lighted by electricity, and Messrs. Challoner have been entrusted with the installation.

DUBLIN.—Messrs. Edmundsons, of London and Dublin, have installed a large temporary plant for electric lighting for a Bazaar held this week in Dublin, to which the distinctive title "Araby" has been given. The Bazaar was held on the extensive premises of the Royal Dublin Society at Ball's Bridge, in aid of the funds of a local hospital. The lighting plant consisted of steam and gas engines equal to 150 H.P., supplying power for about 1,000 incandescents, 22 arcs, and two 20in. search-lights. The lighting gave every satisfaction, and added materially to the success of the Bazaar

GLASGOW.—The Works Committee of the Clyde Trust have had under their consideration for some time the question of lighting and crane accommodation for the new Sessnock Dock. Some time back a report was submitted to the Committee containing information collected from English and Continental sources giving comparative values of electrical and hydraulic appliances. The report further recommended that an electric light installation should be put down for lighting the Dock, and that the plant should be provided to work nine cranes on the south quay of the north basis, and tenders were invited for 35cwt. hydraulic cranes and the plant for working them, and alternatively tenders for nine 35 cwt. electric cranes and complete electric plant and apparatus. Twelve tenders were subsequently sent in for the hydraulic plant and 20 for the electric; but the tenderers furnished no data as to the cost of working and maintenance. An examination of the tenders showed that the initial cost of the electric plant would be much greater than that of the hydraulic, and the Works' Committee, therefore, recommended the adoption of hydraulic machinery, and have recommended the tender of Messrs. Fullerton, Hodgart, and Barclay (Limited), of Paisley, for acceptance. The Committee of Management, which includes all the members of the Clyde Trust, have approved the recommendation, and the consideration of the mode of equipping the remainder of the dock has been remitted to the Works' Committee.

HAMPSTEAD.—On Wednesday the ceremony of placing a memorial stone at the electric lighting buildings now approaching completion was carried out by Mr. Churchwarden Thwaites, Chairman of the Electric Lighting Committee of the Hampstead Vestry, who, at a dinner subsequently held, stated that the cost of the electrical plant for lighting the compulsory area is £19,794, and the cost of the building £7,500, out of a total estimated ultimate outlay of £80,000.

HONOURS.—Amongst the honours distributed by the Queen on the occasion of her official opening of the Manchester Ship Canal, this week, is a knighthood to Alderman W. H. Bailey, Mayor of Salford, and head of the firm of W. H. Bailey and Co. (Limited), Albion Works, Salford.

——— In the deluge of birthday and miscellaneous honours now occurring, Mr. Richard Tangye, head of the Cornwall Works, Birmingham, secures a knighthood.

KILLARNEY.—At a meeting of the Board of Governors of the Killarney District Lunatic Asylum, the question of introducing the electric light was again discussed, and the voting on a resolution proposing that a former decision agreeing to the introduction of electricity be rescinded resulted in a tie. As a doubt arose on the legality of the Chairman giving a casting vote, the decision of the matter has been left for a further meeting.

LLANDUDNO.—The Town Commissioners have passed a resolution opposing the proposal to adopt electric lighting for the town, being of opinion that the question of electric lighting should be adjourned till the reconstitution of the Board in November.

LOWESTOFT.—In reply to a question from Councillor Capps as to the advisability of applying for a Provisional Order, the Mayor stated that a paragraph in the Parliamentary Committee's report notified that the surveyor had been directed to have the replies made to his inquiries on the subject of the cost of gas and electricity tabulated and printed and circulated amongst the members.

MILL LIGHTING.—The extensive range of buildings forming the timber mill of Messrs. Leyland, O'Brien and Co., at Auckland, has been lighted throughout by electricity. The works are frequently running night and day. Messrs. A. and G. Price have carried out the installation, which has given every satisfaction.

NEW BRIGHTON.—The proprietors of the Palace, New Brighton, have recently lighted the building inside and out by the electric light, the work having been entrusted to Messrs. A. Hall and Co., of Liverpool. The installation comprises a Crossley engine driving a 300-light dynamo.

NORWICH.—In a discussion which arose on the question of accepting the tender of the British Gas Light Company for lighting the public lamps for the ensuing year, Mr. Alderman Wyld remarked that there was at present a monopoly of street lighting so far as the Gas Company was concerned; but the success of the use of the electric light in St. Andrew's Hall during the 25 organ recitals recently given, had resulted in a saving of from 20 to 25 per cent., as compared with the gas lighting, and this result would, in the near future, lead to a more careful consideration of the question of lighting than had hitherto been attempted.

OXFORD.—Messrs. Drake and Gorham have obtained the contract for lighting the University Galleries extensions at Oxford. A number of arc and about 70 incandescents will be used.

PROVISIONAL ORDERS.—The Bill confirming the Provisional Order applied for by the Grimsby Corporation to supply electricity throughout the Grimsby district has passed the Examiners on Standing Orders of the House of Commons.

ST. PANCRAS (LONDON).—The Electricity and Public Lighting Committee report to the Vestry that, after consideration of the question of the charges made for lighting the public lamps by electricity, they are in a position to recommend that the price be reduced from the present charge of 6d. to 5d. per unit after the Michaelmas quarter. It was explained that this charge includes the supplying of carbons, labour, trimming the lamps, and repairs and maintenance, charges which altogether amount to 15 per cent. on the amount. At the meeting on Wednesday of the Vestry the recommendation of the Committee was adopted.

SALISBURY.—Mr. W. H. Gramshaw submitted a scheme at the last meeting of the Town Council for the formation of a local company to supply electric current within the city, and asked the Council for their consent to his application for a Provisional Order to be applied for before July 1st. Permission has been given the promoters of the Company to acquire the old town mill as a site for a central station. After discussion it was decided to adjourn the consideration of the scheme for a week in order to test public opinion on the matter and to obtain further details from Mr. Gramshaw.

SHREWSBURY.—At a special meeting of the local gas company, Mr. Spencer Phillips (who presided), in asking the proprietors for permission to borrow £10,000 additional capital, said they had heard a good deal about the electric light, but the Company did not look upon it as an enemy, or even as a friendly rival; they rather hailed with pleasure its advance. There was not a single town in England where the electric light had been introduced that had not had its gas consumption remarkably stimulated.

SOUTHAMPTON.—At the last meeting of the Harbour Board the Works Committee reported that they had received a letter from Mr. Kerbey Bowen confirming the arrangement agreed upon as to the supply of electric power to launches, and that they had given instructions for the electric lighting of the pier and the pavilion, to be carried out by the Board's own labour. The report was adopted by the Board.

SYNAGOGUE LIGHTING.—A new synagogue at the West End of London has just been lighted throughout by electricity, the expense being borne by Mrs. J. L. Hart. The current is taken from the mains of the Metropolitan Company. Mr. Schultz, engineer to the Notting Hill Company, superintended the installation, the contractors being Messrs. Money and Nash.

TAUNTON.—Mr. J. H. Smith, the Borough Electrical Engineer, has presented his report to the Town Council, which states that an increase in customers has taken place since the last report, equal to an increased demand for current for 248 8-c.p. lamps.

Telephonic Communication in Costa Rica.—The Government of the Republic of Costa Rica has recently granted a ten-years' concession for the establishment of a system of telephones in that country. Under the concession, all material and apparatus required for the system will be admitted free of import duty. The Government may acquire the system one year after it is established by paying the concessionaire the cost of installation and 50 per cent. more by way of indemnity; after the second year 25 per cent.; after the third year 15 per cent.; after the fourth year 10 per cent.; and during the fifth year the cost of installation only.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS AND REPORTS.

West Coast of America Telegraph Company (Limited).

The following is the report of the Directors of this Company for the year ended December 31st last to be presented at the Seventeenth Ordinary General Meeting, to be held at 50, Old Broad-street, E.C., on Tuesday, the 29th inst., at 12:30 o'clock :—

The gross income for the year 1893 was £15,096. 4s. 3d., as against £22,218. 16s. 9d. in 1892, and, in order to make up the loss on the year's working, and to meet the Debenture coupons, it was necessary to take £16,536. 12s. 3d. from the reserve. The traffic handled in 1893 was larger than in the previous year, but owing to the fall in the rates of exchange both in Peru and Chile, which continued throughout the year, the sterling value of the receipts was considerably depreciated. The total expenses were £19,632. 16s. 6d., against £21,919. 14s. 8d. in 1892, a saving of £2,286. 18s. 2d.

The cable between Valparaiso and Talcahuano, 267 nautical miles, was successfully laid by the Company's steamer "Retriever," and opened for traffic on October 1, 1893. A landline connects Talcahuano with the City of Concepcion. This addition to the system of the Company was effected at a total cost of £29,699. 4s. 3d. The traffic carried over this line, in the short time it has been open, is satisfactory. The landline between Buenos Ayres and Valparaiso, constructed by the Pacific and European Telegraph Company (Limited), was opened for traffic on March 19, 1894. The completion of this line restored the direct service between the Company's stations and Europe *viâ* Madeira.

The Directors regret to report the loss of an esteemed colleague through the death of Mr. Henry Roberts. Mr. J. Denison Pender and Mr. Frederick Walters retire from the Directorate, and offer themselves for re-election ; as does the auditor, Mr. John Francis Clarke.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to February 9th, was not filed till May 4th, when the whole nominal capital of £7,000,000 stock was fully paid up.

BENHAM AND FROUD (LIMITED).—The annual return of this Company, made up to May 9th, has been filed. Out of a nominal capital of £50,000, in shares of £10 each, 2,907 have been taken up, and the full amount per share called, resulting in the payment of £28,947. 10s., and leaving £122. 10s. in arrear.

BIRMINGHAM HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED). The annual return of this concern, made up to January 11th, was recently filed. Seven Ordinary and 100 Founders' shares have been taken up, the latter being issued as fully paid to the House-to-House Electric Light Supply Company (Limited), of Richmond-road, Earl's Court, London, S.W. No calls have as yet been paid on the Ordinary shares.

[Similar returns have been filed of the Midland, the South of England, and the Western House-to-House Electricity Companies.]

CORLETT ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return of this Company, made up to May 14th, has been filed. The nominal capital is £10,000 in shares of £10 each, of which 620 have been taken up. Of these 100 have been issued as fully paid, while upon the remainder the full amount has been called and paid.

PHOSPHOR BRONZE COMPANY (LIMITED).—The annual return of this Company, made up to April 13th, was recently filed. The nominal capital is £150,000, divided into 15,000 Ordinary and 15,000 Preference shares of £5 each. 7,335 of the former and 8,375 of the latter have been taken up, and the full amount per share called, resulting in the total payment of £78,550. It is stated that no less than £11,560 has been paid on 1,156 forfeited shares.

A. RANSOME AND CO. (LIMITED).—The first annual return of this Company, made up to April 27th, shows that the whole nominal capital of £59,000, in £10 shares, has been taken up. Of these, 5,593 were issued as fully paid, and the full amount has been called and paid on the remaining 307 shares.

RANSOMES, SIMS AND JEFFERIES (LIMITED).—The annual return of this Company, made up to April 26th, shows that out of a nominal capital of half a-million in £100 shares, 3,075 have been taken up. Upon 2,185 of these the full amount has been called, while upon the remaining 890 shares a call of £50 per share has been made, resulting in a total payment of £263,000.

SOUTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED). The annual return of this Company, made up to April 18th, has been filed. The nominal capital is £30,000, divided into 4,000 Preference and 2,000 Ordinary shares of £5 each ; 50 Preference and 708 Ordinary have been subscribed for and allotted, and the full amount called on each share. The calls paid have realised £3,735, while £55 has yet to be sent in.

YORKSHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).— The annual return of this Company made up to March 20th, has just been filed. Out of a nominal capital or £100,000, divided into 19,900 Ordinary and 100 Founders' shares of £5 each, 10,000 Ordinary and the Founders' shares have been taken up, and all the latter issued as fully paid. Upon 7,366 Ordinary shares the full amount has been called, and upon the remaining 2,634 shares a call of £2 per share, has been made, resulting in the payment of £41,900. 10s., and leaving £197. 10s. in arrear.

CITY NOTES.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended May 20th were £907, as against £794 in the corresponding period of 1893, being an increase of £113. The total receipts for the half-year amount to £18,212, as against £17,735 for the corresponding period of 1893, an increase of £477.

RUSTON, PROCTOR AND CO. (LIMITED).—The results of trading for the year ended March 31st last shows a total balance of £48,940, which, by allowance for depreciation of plant and machinery of the small sum of £3,232 and Directors' remuneration, leaves £44,531 for distribution. £18,750 has already been distributed in interest on debentures and interim dividend, and it is now proposed to pay a further dividend of 10s. per share, free of income-tax (making $7\frac{1}{2}$ per cent. for the year), and after allowing £10,000 in reduction of the goodwill account, carrying forward £3,281 to next account. The Directors' report states that the buildings, plant, and machinery have been well maintained out of revenue, and the usual provision made for ascertained or probable bad debts. A meeting of shareholders takes place at the Sheaf Iron Works, Lincoln, on Tuesday, the 29th inst., at 2:30.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—Notice is given that the coupons due June 1st next on the Five per Cent. Registered Debentures of this Company (bonds Nos. 1 to 10,000) will be paid on and after that date at the banking house of Messrs. Prescott, Dimsdale, Cave, Tugwell, and Co., 50, Cornhill, E.C., or at the Royal Bank of Scotland, 123, Bishopsgate-street Within, E.C. Coupons have to be left three clear days for examination, and the register of debenture holders will be closed from the 25th to the 31st inst. inclusive.

THOMAS PARKER (LIMITED).—A prospectus has been issued this week inviting applications for 3,000 shares of £10 each in Thomas Parker (Limited), which is formed (according to the prospectus) to carry on the business of manufacturers of plant for electric lighting, electric transmission of power, electro-chemical, electro-metallurgical, and other purposes. The nominal capital of the Company is £75,000, in £10 shares. The vendor and promoter is Mr. Thomas Parker, F.R.S.E., M.I.C.E., M.I.M.E., M.I.E.E., "Mechanical and Electrical Engineer, Founder and Managing Director of Elwell-Parker, Limited, and for five years Works' Director and Chief Engineer of the Electric Construction Corporation (Limited)." For a list of important works and machinery designed and superintended by Mr. Parker and the Electric Construction Company's staff we must refer our readers to the prospectus, which further states that the Directors anticipate "an immediate turnover of £100,000 a year," although the prospectus is more than usually sparing of details. It is stated that the Eickemeyer winding patents are assigned to the Company by the vendor, who receives £25,000 in all, £17,500 in fully paid shares and £7,500 in cash. The vendor contracts to act as Managing Director to the Company for 10 years. The prospectus contains a waiver clause, which does not, however, affect the contract for sale.

In reference to the Eickemeyer patents referred to in the prospectus of Thomas Parker (Limited), Mr. James Gray, Secretary of the Electric Construction Company, writes : "One of the chief inducements which is held out to subscribers is the acquisition of the Eickemeyer patents for winding dynamos ; but the prospectus makes no mention of the fact that these patents are in Mr. Parker's hands subject to a general licence in favour of my Company for the whole of the United Kingdom. The statement in the prospectus that 'Mr. Parker and his staff designed and superintended' certain works is misleading, as only a portion of our staff employed upon the works in question has joined Mr. Parker since the Board of my Company dispensed with his services. We have reason to believe that we shall have to claim certain of the other patents which it is represented on the prospectus will be transferred to the proposed Company, as having been taken out by our employés. The whole matter has been placed in the hands of our solicitors, Messrs. Linklater and Co."

The following letter is also sent by Mr. W. A. Gibbs, of the Otis Elevator Company, in reference to the Eickemeyer patents :—"In the prospectus of Thomas Parker (Limited), among the 'advantages with which the Company start,' we find in the fifth paragraph a statement that 'the vendor has acquired, and will assign to the Company, the Eickemeyer patents for winding, &c.' It may be well to explain that the Eickemeyer patents cover machines designed for elevator or lift purposes, as well as machines for traction purposes, and I deem it well, therefore, to state explicitly that those Eickemeyer patents which refer to elevators or lifts are in the exclusive possession, by assignment, of this Company."

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee for an official quotation for vendors' shares, Nos. 7 to 214 and 719 to 10,000 of the Charing Cross and Strand Electricity Supply Corporation (Limited).

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 837.—Vol. XXXIII. FRIDAY, JUNE 1, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

What is everybody's business is, as usual, nobody's business, and although the glow lamps have been freed from monopoly for six months, and better quality was promised as well as better price, no tests of efficiency, life, or candle-power have been published, and only the vaguest rumours are current about the relative merits of the principal varieties now on the market. The Kensington and Knightsbridge Company have, in the interests of their customers, and of the popularity of electric lighting, conducted tests of initial candle-power, watts, and degree of vacuum, and on the strength of these tests recommend and sell such lamps as they think will give the greatest satisfaction. The information which they have obtained, but which is hardly suitable for publication (since it would be devoid of interest if the makers' names were omitted) is rather surprising. Eight-candle lamps nominal are found to be anything between ten or six candles, and nominal watts per candle are equally erratic, the vacuum is in some cases very poor.

Hitherto the only useful information on the subject of English lamps, that is to say, lamps which *were* available for use in this country, has been the very complete and valuable series of tests made under the direction of Prof. Ayrton. The chief point, and a very important one, settled by these tests was the relation between volts and candle-power. Life tests have also been made, we understand, under Prof. Ayrton, but nothing has yet been published; perhaps they will appear in conjunction with the tests of lamps which were begun, or were said to have been begun, at the Chicago Exhibition, and which, for all we know, are going on still. We are glad to announce, therefore, that an exhaustive examination of a large number of lamps is now being made by Mr. Preece at the General Post Office. Twelve or more lamps of each make are being run continuously, and others for a few hours a day, and daily tests are being made of candle-power and watts; the lives are of course accurately noted. The results, which we have been permitted to inspect, are in some cases very satisfactory. A full report of the tests will be communicated to the British Association, and will include the history of more than three thousand hours, if, as is not improbable, some lamps survive through this period.

The announcement in our last issue that the Corporation of Brighton have received tenders for motor-alternators has given rise to the idea that the electrical engineer to this body, who has for some years been a staunch convert to continuous currents, was going to supply outlying districts with continuous currents generated through the intervention of high-pressure, alternate-current transmission. But a motor-alternator is not an alternate-current motor; and Mr. Arthur Wright probably holds the very sensible view that there is nothing that an alternate-current motor can do, that cannot be done equally well by continuous current. No continuous-current man, with the exception, we believe, of one who was concerned with the original, and now abandoned, design of the Brighton station, has ventured to say that alternate currents are of no use at all, and Mr. Wright, finding that certain residences which are too distant and scattered for connection with a three-wire network, must be supplied by alternate-currents and house transformers, if supplied at all, has readily adopted this system; but as it is not worth while at present to put down an alternating plant in this station, alternators will be driven at a sub-station by means of continuous-current motors fed from the three-wire service.

We print this week an abstract of the discussions which took place in New York and in Chicago on the Paper by Mr. Farnham dealing with the electrolytic corrosion of gas and water pipes, and published in our issue of May 4th. The Chicago meeting was, on the whole, the more fruitful in practical contributions to the solution of the problem under discussion. The three-wire system, as used at Portland (Oregon) and Bangor (Maine) would appear to be a singularly neat and effective method of reducing earth leakage and electrolytic corrosion to a minimum, without at the same time reducing shareholders' dividends to zero. Nothing, perhaps, was more remarkable in this debate than the decided leaning to the double-trolley system. It seems but yesterday that the mechanical, electrical, and financial impossibility of this mode of working was demonstrated by the entire electrical press of the United States, with all the logical completeness of a problem of Euclid. Now, it is genially hinted that nothing but the influence of a single electrical manufacturing concern prevented the number of trolley wires in America from being double their present figure. Misery, we know, acquaints a man with strange bedfellows, but we must confess never to have anticipated that electrolytic corrosion would acquaint our transatlantic friends with the virtues of the double-trolley system.

A communication from the University of Wisconsin gave a plausible theory, based on actually observed effects and experi-

Digitized by Google

ments, accounting for the large amount of corrosion which apparently takes place with such absurdly low differences of potential as 0·001 volt. Another less scientific, but possibly equally true and certainly more comforting hypothesis was that the gas people themselves must take a large proportion of the blame, filling as they do the earth surrounding their leaky pipes with "ammonia and other destructive products of the gas retort." Seriously speaking, however, electric traction engineers, whilst squarely facing this matter, will do well, even in the States where motor cars appear to be a prime necessity which is not the case with us, not to allow too tamely the implication that before their day corrosion was a disease which never afflicted underground metallic structures.

It is one of the strongest confirmations of the truth of any physical generalisation, when a deduction from it in regard to any one particular phenomenon is justified by subsequent experimental investigation. A fresh instance of this fact occurs in the case of recent deductions which have been made from the periodic law of chemical elements. According to this law, there is a definite harmonic relation between the atomic weights and the physical and chemical properties of the elements and certain of their compounds. Bearing this fact in remembrance, Mr. A. J. Wurtz has endeavoured to deduce the associates of the elements which he has experimentally proved to be non-arcing. As may have been expected, his deductions proved to be perfectly sound; for the deduced associates have turned out, on trial, to possess this same property of non-arcing. Mr. Wurtz has recently published some further particulars of his researches in this direction, and of the application of these non-arcing metals to lightning arresters. Chemical science is rapidly taking its place among the deductive sciences, especially in its relation to atomic quantities; and it seems more than probable that Mendelejeff's—or was it Newland's?—great generalisation has many more hidden facts, the discovery of which would prove useful to engineers, scientists, and mankind in general.

Some experiments have lately been undertaken by the Munich Gas Company with a view to test the suitability of the Welsbach system of street lighting. There has been plenty of glorification of the incandescent gas-burner on the part of its advocates; but we have failed to discover any reliable and systematic trials which prove that, when the rapid depreciation of the burner and frequent breakage of the chimneys is included, the cost is less than that of ordinary gas-burners. As might have been expected from the short life of these Welsbach burners, even under the favourable conditions of interior lighting, the experiments at Munich show the utter unfitness of the incandescent gas-burner when exposed to rough treatment, such as is inevitable in open-air lighting. Three different forms of lantern and of igniting apparatus were used in these trials. In the "Berlin" lanterns the ignition was by means of a pilot jet, burning against the Welsbach mantles; and in two months no less than 14 mantles and 25 chimneys were used as renewals for four burners. This represents maintenance at the rate of 21 mantles and 38 chimneys per burner per annum. Electric spark igniters were tried, and gave good results in fair weather, but failed when the air was damp. When the pilot gas jet was placed in the most favourable position, it was found that the depreciation was at the rate of three or more mantles per burner per annum. Moreover, it is found to be necessary to keep two sets of men engaged in looking after the lamps: one set for lighting and extinction, the other set for repairing the defects which frequently manifest themselves. In this way the cost of attendance is raised to a much higher figure than even with ordinary gas burners; while it is, of course, enormously greater than with electric lighting.

The project for the Chicago and St. Louis Electric Railway is getting on as well as can be expected. The mail brings us a batch of American electrical papers, in which we see that the scheme has advanced as far as half-tone illustrations of the passenger car and the motor truck. There is, however, a suspicion about these pictures of their having been photographed from one-inch-to-the-foot models standing on an office table. The distance between Chicago and St. Louis is considerable, but experience will probably show that it is not greater than that between newspaper illustrations of models and the completion of the actual project.

Institute of Chemistry of Great Britain and Ireland.—An examination in practical chemistry for the membership will be held in the laboratories of the Institute, 30, Bloomsbury-square, W.C., on Monday, July 2nd, and following days.

Muirhead v. Commercial Cable Company.—We are informed that the Commercial Cable Company will appeal from the decision of Mr. Justice Kennedy. There are over 50 cases on the appeal list in front of this, so that it will possibly not come on for hearing until after the Long Vacation.

The Zédé Electrical Submarine Boat.—A telegram from Toulon states that a fire has occurred on board the submarine boat "Gustave Zédé," by which two electrical engineers were half suffocated. The boat sustained serious damage, and had to be sunk.

Cable Interruptions and Repairs:—

	Date of Interruption.		Date of Repair.
Cayenne Paramaribo	Oct. 25, 1893	......	May 29, 1894.
Bissao-Bolama	Nov. 24, ,,	......	—
Brest-St. Pierre (P.Q. Co.) ...	Mar. 29, 1894	......	—
Accra-Kotonou	Apr. 1, ,,	......	—
Lagos-Accra	May 21, ,,	......	—

The Hermite Process of Sanitation.—We have received a copy of the "Reports of the *Lancet* Special Analytical Sanitary Commission on the Hermite Process of Sewage Treatment by Electricity," which has been reprinted from the *Lancet*, May 26, 1894. Copies of these reports may, we understand, be obtained at the office of the *Lancet*, 433, Strand, W.C.

Technical Education.—The *City Press* says that in consequence of the large increase in the number of students at the Finsbury Technical College, the Governors of the City and Guilds of London Institute propose to extend the buildings by taking in additional premises at a rental of between £500 and £600 a year. Upon the alteration and adaptation of the premises it will be necessary to expend about £4,000.

Return Currents.—In a recent number of the *Boston Herald*, Mr. H. C. Cushing, jun., an electrical inspector for the Boston Board of Fire Underwriters, cites several instances where electric currents of considerable strength have been carried into buildings through gas or water pipes. Mr. Cushing states that in the basement of one building a man obtained a current of 25 amperes at 8 volts by simply twisting his wires around two different water pipes which entered the building.

Digitized by Google

Sunderland.—Prof. Kennedy has presented his report on the proposed electric lighting of this town to the Corporation. From the plans sent him he judges that the suggested arc lighting will replace 80 ordinary street lamps, and about 12 100-c.p. Sugg lamps. At 60 yards apart, he makes out that about 50 lamps will be required. He estimates the cost at £40 a year for all-night lamps, and £20 for half-night lamps. The total would be £1,500 per annum. On the whole, at the lowest estimate, the cost of arc-lighting would be about £550 per annum more than the cost of gas, but the amount of light in the streets would be at least 20 times as great as at present.

Search-Light Manœuvres.—Experiments with the electric search-light were carried out by the naval and military authorities at Cremyll on Friday last and again on Saturday night. On Friday evening the lights were fixed on the beach, but on Saturday night they were removed to the Garden Battery at Barnpool, and the dynamos of H.M.S. "Scourge," moored in the pool, kept the light going. Two torpedo boats belonging to H.M.S. "Defiance," torpedo schoolship, which had been previously sent outside the Breakwater, attempted to force an entrance to the harbour and the light was brought to play on them, not only for the purpose of detecting them but to enable the military authorities to photograph them.

Royal Society.—The following Papers were down for reading yesterday:—Dr. J. Hopkinson, F.R.S., and E. Wilson, "Propagation of Magnetisation of Iron as affected by the Electric Currents in the Iron;" Lord Kelvin, P.R.S., and Magnus Maclean, "On the Electrification of Air;" P. Cardew, "Note on the Possibility of Obtaining Unidirectional Current to Earth from the Mains of an Alternating-Current System;" S. Bidwell, F.R.S., "On the Effect of Magnetisation upon the Dimensions of Iron Rings in Directions Perpendicular to the Magnetisation, and upon the Volume of the Rings;" H. Tomlinson, F.R.S., "The Effect of Mechanical Stress and of Magnetisation on the Physical Properties of Alloys of Iron and Nickel and of Manganese Steel."

Step-Up Centrifugal Pumps.—In order to avoid the necessity of transforming circular into rectilinear motion in the case of electric pumps operating under high lifts, Messrs. Dumont, of Lille, have adopted a rather interesting expedient. On each side of the motor, and fitted to the same bedplate, two centrifugal pumps are mounted, the fans of which are keyed on the armature shaft of the motor. The whole four of these pumps are mounted in series, that is to say, the discharge pipe of the one pump is connected to the inlet of the other, so that the final difference of head between inlet to the first pump and the discharge pipe of the last, is the sum of the heads due to the four pumps taken separately. The plant in question was supplied to the Altai Mines, and the total lift is about 160ft.

Thunderstorms.—On Saturday afternoon last a violent thunderstorm passed over Bridgwater. The captain and mate of the ship "Sarah," of Gloucester, took refuge from the storm under a tree on the river bank, and both were struck by lightning. The latter was killed instantly, his body being greatly disfigured, but the skipper escaped without serious injury. During the storm at Highbridge, in the same district, several sheep which were grazing in a field were killed by lightning, and a deep furrow is said to have been ploughed up for some distance across the field. At Malvern a church steeple was struck, and received considerable injury, and the parish church of Bromsgrove was similarly damaged. At Mollington, near Chester, the thunderstorm did considerable damage, wrecking a portion of a house, and injuring a man and child.

Atmospheric Electrification and Snow.—According to the second yearly report of the Sonnblick Society, in addition to the regular meteorological observations special attention is paid by the observer, P. Lechner, to investigations of atmospherical electricity, and some interesting results have been already obtained. It is found that the electric condition of the earth at the summit remains nearly constant during clear days throughout the year, so that, owing to its height and configuration, it is free from the daily and yearly fluctuations of electricity which are observed on the earth's surface at lower levels. It would be interesting to know whether this has also been observed at other mountain stations. The observations of St. Elmo's Fire have shown the interesting fact that when snow falls in large flakes the electricity is almost always positive; but when the snow consists of dust-like particles, negative electricity is developed.

The Fleuriais Electric Log.—In 1878, Admiral Fleuriais, of the French Navy, brought out an electric log, which was tried on the "Magicienne." It may be described as a small water-mill with a wheel consisting of cross-arms tipped with cups like an anemometer. As the cups revolved in the water while the ship moved, a contact on the axle interrupted an electric current flowing through a wire between the ship and the log, and sounded a telephone. The note given out by the telephone was a measure of the number of revolutions per minute of the log and the speed of the ship. At high speeds, however, the ear was not quick at recognising the note, and Admiral Fleuriais has substituted for the telephone an electric bell, which is struck every 24 revolutions of the mill-wheel or vanes. By timing the interval between two strokes of the bell the speed of the ship is obtained. The apparatus has been tried on board the "Océan" and other men-of-war, and recently adopted by the Minister of Marine.

Electrical Traction and Variable Speed Gear.—The experience of the past few years has been that electrical engineering problems of the greatest difficulty and importance have passed into the hands of mechanical engineers. Electricians have been slow to recognise the importance of the mechanical element in matters of electrical engineering. In connection with electrical traction, we have often referred to the importance, indeed, the necessity, for variable speed gear, if electric traction is to become a commercial thing. Now, we learn that a very powerful rival to electrical traction, namely, the Gas Traction Company, knowing the importance of what we have urged, has secured an exclusive licence to use the Beaumont variable power gear for gas and oil traction purposes on tramways and light railways. For electrical traction it is, if anything, more important that variable power gear should be used. The Gas Traction Company will now only use one gas-engine to each car, instead of two to each car, and in the same way tramcars might be fitted with about half the motor power now required, if this gear were employed, and there would be a corresponding saving in the generating station.

Institution of Civil Engineers.—At the annual general meeting of this Institution on Tuesday, the tabular statement of the transfers, elections, deaths, and resignations during the year showed an effective increase of 188 on the previous total of 5,371, while, as regards the students, the decrease was 28. The total receipts amounted to £25,576. The general expenditure has been £17,489 (including £8,050 for publications). A sum of £10,000 has been placed on deposit to meet the considerable sums which will be required at an early date in connection with the new building. The summary of investments showed that there altogether stood to the credit of the Institution £133,673. A decision has been arrived at to utilise the sites of Nos. 24, 25, and 26, Great George-street, and designs for a new building had been prepared by Mr. Charles Barry, F.R.I.B.A. It is hoped that the work may be commenced early in the recess. The ballot for Council resulted in the election of Sir Robert Rawlinson, K.C.B., as President; of Sir B. Baker, K.C.M.G., Mr. J. W. Barry, Mr. W. H. Preece, C.B., and Sir Douglas Fox as Vice-Presidents; and of Dr. W. Anderson, A. R. Binnie, W. R. Galbraith, J. H. Greathead, Sir Chas. A. Hartley, K.C.M.G., J. C. Hawkshaw, C. Hawksley, Dr. Alex. B. W. Kennedy, Sir Bradford Leslie, K.C.I.E., J. Mansergh, Sir Guilford Molesworth, K.C.I.E., Sir E. J. Reed, K.C.B., W. Shelford, F. W. Webb, and Dr. W. H. White, C.B., as other members of Council.

The Manufacture of Engineers.—A correspondent of *The Engineer* discusses the relation of technical colleges to the present enormous output of "engineers," and we make the following extract from his letter:—

"I have not a word to say against technical education for working men: I speak of something much higher. Take, for example, the engineering schools in connection with University College, King's College, and so on. Every day new workshops with most costly laboratories are being opened

Digitized by Google

with a great flourish of trumpets and beating of drums. Lord Kelvin opened one at Cambridge on Monday week, for example. Sir Frederick Bramwell hinted in the course of the proceedings that there might be too many of these things already. I wish he would speak out. All these places compete with each other. They supply employment for professors and demonstrators. The competition for the chairs is enormous; work must be found for these gentlemen, and no stone is left unturned to get pupils. This has gone on now for some years, and is going on still. Now, I hold it is time the truth was made known. The truth is that hundreds of young men are turned out who are believed by their parents, and also by themselves, to be engineers. My standard of an engineer is that the man calling himself one should be able to do work for which he can get paid. Putting this in a very coarse way, I hold that a man is not an engineer unless he knows enough to make his bread by engineering. That is precisely what 90 per cent. of the college-trained youths cannot do. No college can give that training which alone imparts commercial value to a man. But let me suppose that the contrary is the case, and that every youth who has had three years' training in a technical college—not school, observe—is really competent in the fullest sense of the term, what follows? I am sure I am not over the mark when I assert that about 2,000 young men are turned out of the colleges of the United Kingdom every year who are 'engineers.' Where on earth is this host to find work?"

Magnetic Properties of Soft Iron at Different Temperatures.—At a recent meeting of the Société Française de Physique, M. Curie read a Paper on the magnetic properties of soft iron at temperatures between 20deg. and 1,350deg., and for magnetising forces of 25 to 1,350 units. He has drawn a series of curves showing the connection between the magnetising force and the intensity of magnetisation at different temperatures. For magnetising forces up to 1,300 units the different curves do not differ much, but for higher values of the magnetising force they separate to a more marked degree. For temperatures between 756deg. and 1,375deg. the curves obtained are straight lines passing through the origin, showing that between these temperatures the susceptibility is a constant and independent of the magnetising force. The author has also plotted a series of curves connecting the intensity of magnetisation (I) and the temperature, the magnetising force being constant. The value of I is at first constant as the temperature rises, then it diminishes faster and faster till the change becomes most rapid at a temperature of about 745deg. Above this temperature the rate of change of I diminishes. Between 950deg. and 1,210deg. the value of I only diminishes slowly, while at a temperature of 1,280deg. it increases suddenly, and then as the temperature goes on increasing it gradually diminishes. The author finds that at any given temperature the value of I obtained is independent of whether this temperature has been reached by warming the body or by cooling.

Electrical Resistance of Alloys.—An interesting Paper by M. van Aubel, on the electrical resistance of some new alloys, was recently read before the Société Française de Physique. In the first place the author gave some particulars about a form of steel called "kruppin," manufactured by Herr Krupp, at Essen. This alloy has a specific resistance of 84·7 microhms at 18°C., or of 85·5 if the sample has been heated for several days. The mean coefficient of variation of the resistance with temperature decreases slightly with increase of temperature, but is always nearly equal to +0·0007. This body, although it has relatively high specific resistance (that of german silver being 20·76), can be heated to a temperature of 600°C. without change of structure, and can be obtained in the form of wire or sheet. The author also gave particulars of the experiments made on some nickel alloys manufactured by Messrs. Fleitmann, Witte and Co., of Schwerte (Westphalia). One of these alloys (marked I_a I_a) has when hard a specific resistance at 20°C. of 50·2 microhms and a temperature coefficient of −0·000011, while when soft its specific resistance is 47·1 microhms and its temperature coefficient +0·000005. This alloy may prove of considerable practical utility, although if it is found that its thermoelectric power with reference to copper and brass is, as is generally the case with these alloys, at all great, this will in a great measure prohibit its use in cases where great accuracy is required. During the discussion on the above Paper M. Guillaume mentioned that an alloy of 68·6 parts copper, 30 parts manganese, and 1·3 parts of iron has a specific resistance of 108 microhms, while its temperature coefficient is very small, even passing from positive to negative as the temperature rises. He also mentioned that the difficulty of the high thermoelectric power with reference to copper could be overcome if the wires are soldered to plates of the same alloy, which are in turn soldered to the copper connectors of the resistance boxes or Wheatstone bridges.

The Supply of Electricity at the Chicago Exhibition.—The following report on the supply of electricity at the Chicago Exhibition has been presented by Mr. H. D. Wilkinson, the Director of the British Section, to the Royal Commission:—

It was by the division of the whole lighting scheme into sections for which contracts were entered into with different nationalities, that the lighting at Paris in 1889 was such a representative display. With one or two exceptions, notably in the case of Messrs. Siemens and Halske, who had the contract for lighting the terminal station, the whole of the electrical power plant was American. Secondly, in the electrical building, no steam was furnished or allowed, the idea being that electrical power alone was appropriate to use. This secured a grand display for the electrical transmission of power, but was fatal to a large class of exhibits of great importance. Practice in both lighting and power is now almost entirely in direct coupled engines and dynamos, and such coupled plant here exhibited could either not be run at all, or had to be run by making the dynamo a motor to turn the engine. This affected our section in three exhibits. The general lighting of the various buildings was by arc lamps run in series on direct current circuits, but for all incandescent lamps and arc lamps required by exhibitors the supply was by high tension, alternating current with transformers. The high-tension wires at 2,500 volts were carried through subways to the principal points in the grounds, and from transformer pits located at points along the route current at 100 volts was taken into the various buildings. The contract for the supply of this current was in the hands of the Westinghouse Electric Company. The charge made by the Exposition Company for the use of lamps for six months was as follows:—Per incandescent lamp of 16 c.p, $8; per arc lamp of 2,000 c.p. $60. To obtain this service the exhibitor had to pay the above in advance, together with the cost of making connection, wiring and fixing lamps, viz.:—Per incandescent lamp $3·50, per arc lamp $3·50. The New York Insulated Wire Company had the exclusive right of putting in all wiring for exhibitors, and instances occurred in our own and foreign sections in which exhibitors had put in their own wiring, but could not obtain current for their lamps until they had paid the above wiring charges to the Exposition. There was great delay in the fixing of exhibitors' lamps, as the first attention had to be given by the Electrical Department to the general lighting of the grounds and buildings, this being very much in arrear. Up to the expiry of the first three months, the full amount of $8 per lamp had to be paid in advance, and claims for rebate on the time of non-supply claimed formally afterwards; but requisitions for light after August were allowed on an advance payment of less than $8 per lamp, according to the time for which light was actually supplied.

A New Conduit Electric Traction System.—At a recent meeting of the American Institution of Civil Engineers, Mr. Albert Stetson described a conduit system of electric traction which he considers capable of meeting the exigencies of the service in American cities. He asserts, says *Engineering*, that the successful solution of the problem is a much more difficult matter in the States than in Europe. In the first place, the extremes of climate are great; secondly, the roadways are in general badly kept; and, in the third place, the narrow tyres common on American pleasure vehicles limit the width of slot which can be adopted. The conduit he recommends is of small dimensions, one 2in. or 3in. wide by 7in. deep answering all requirements. The conduit is slotted, and through this slot pass the rods attaching a contact shoe, which runs in the conduit, to the car, the attachment being so made that in case of a car leaving the rails, the shoe remains behind, without injury either to itself or the conduit. In the conduit two insulated cables are placed, a metallic return being used. These cables run into contact boxes, placed alternately at intervals of 10ft. on either side. In each box is a contact plug, passing through an insulating bush, which, as the shoe reaches it in its passage along the conduit, is depressed, and makes contact with the cable below, thus placing the car in electrical communication with the cable at that point. When the shoe has passed, the contact plug is raised by a spring clear of the cable, and no leakage can then take place between the plug and any snow mud, or dirt which may be in the conduit. The shoe is long enough to extend over at least three of these boxes at one time, and one side of it is thus connected to the positive main and the other to the negative one. Every precaution is taken to prevent sparking in breaking contact in these boxes. The ends of the shoe are insulated, and thus depress the plug into contact to the cable before the circuit is completed from the box through the car. To insure easy working, the boxes are also filled with oil. A test of the system was made, after filling the conduit for a distance of 75ft. with water and mud; under the conditions, it is said, there was practically no leakage, even after four days' submergence.

THE BRIGHTON ELECTRIC SUPPLY STATION.

Brighton claims the distinction of being one of the first English towns in which there was a system of electric lighting from a central station. It was at the commencement of 1882 that Mr. Hammond commenced to supply electric light to that town. In the following year his works were taken over by the Hammond Electric Light and Power Supply Company; and in the same year the Corporation was granted its Order. Many years passed, however, before the Corporation made any efforts to use the Order it had acquired, during which time the Company struggled on against numerous difficulties. In 1885 the name of the Company was changed to the Brighton Electric Lighting Company, and three years later saw it the possessor of the name of Brighton and Hove Electric Light Company. Up to 1889 the Company had been working without statutory authority; while the Corporation had held their statutory authority without working. After this date the Company made effort after effort to acquire the necessary Order; but it was defeated on each occasion through the active opposition of the Corporation. At this date, moreover, the Corporation set about erecting a station and supplying a portion of its statutory area, and from time to time the area of supply was extended. The Company never got its working powers, and it was bought out by the Corporation in January last under the understanding that the Company should continue working until September 30, 1894, during which time the customers of the former will be transferred to the mains of the latter. The first system which was in use by the Brighton Company was the series system, with parallels of lamps on a 10-ampere circuit, Brush arc-lighters being used. Probably in no other instance in the history of electric lighting has this system been so carefully and successfully developed as in the hands of Mr. Arthur Wright at Brighton, automatic regulators, gravity electrostatic voltmeters, electricity meters, fault-locating apparatus, several kinds of automatic switches, and other ingenious devices were in regular use until the series system was superseded in the spring of 1888 by an alternate-current plant. The system adopted by the Corporation is the low-pressure, three-wire, continuous-current system for the greater part of the town combined with a high pressure plant for the outlying parts. The cables of the Company had been carried overhead, while the mains of the Corporation were to be placed underground. Considerable extension of the Corporation mains have been made this year.

We have entered somewhat fully into the history of electric lighting in Brighton, because it is necessary to have some knowledge of this in order to understand the present state of things at the Corporation station, which we shall now describe. Partly on account of this condition of things, and partly because of the careful and scientific way in which the consumer has been induced to use his supply, there exists at the Corporation station a condition of economy and a load-factor which is in the highest degree satisfactory. We have already stated that the three-wire continuous-current system is being used, and we may add that both the street arc lighting and the consumers' lamps are supplied from the same network. The public lighting is at present confined to the sea-front, where there are a large number of well-designed lamp standards and 3,000 c.p. arc lamps. One of these lamp standards is shown in Fig. 1.

In its present incompletely developed state the Corporation station might be rated at about 1,280 H.P., this being the total capacity of the existing plant. But extensions are being rapidly pushed forward; there is floor space enough under the present roof for several hundred more horse-power, and plans are being drawn up for the erection of another set of buildings —boiler-house and engine-room—at the back of the station now fronting on North-road. This satisfactory rate of extension is explained by the rapidity with which customers are being connected, to some extent by transference from the other system, and the others in the usual way. At the end of 1892 not more than 210 houses were connected to the Corporation mains; at the end of last year the number was just double this, or 420, and now there are over 500.

Steam is raised, at a pressure of 150lb., in six Lancashire boilers, 28ft. by 7ft., three of which were manufactured by Messrs. Yates and Thom and three by Mr. Danks of Oldbury. No furnace economiser is used, but the feed-water, which is of a very hard quality containing much chalk, is previously heated by the exhaust steam, in two feed-heaters placed at the back of the boiler-house and close to the chimney. The whole of the exhaust steam can be used for this purpose as,

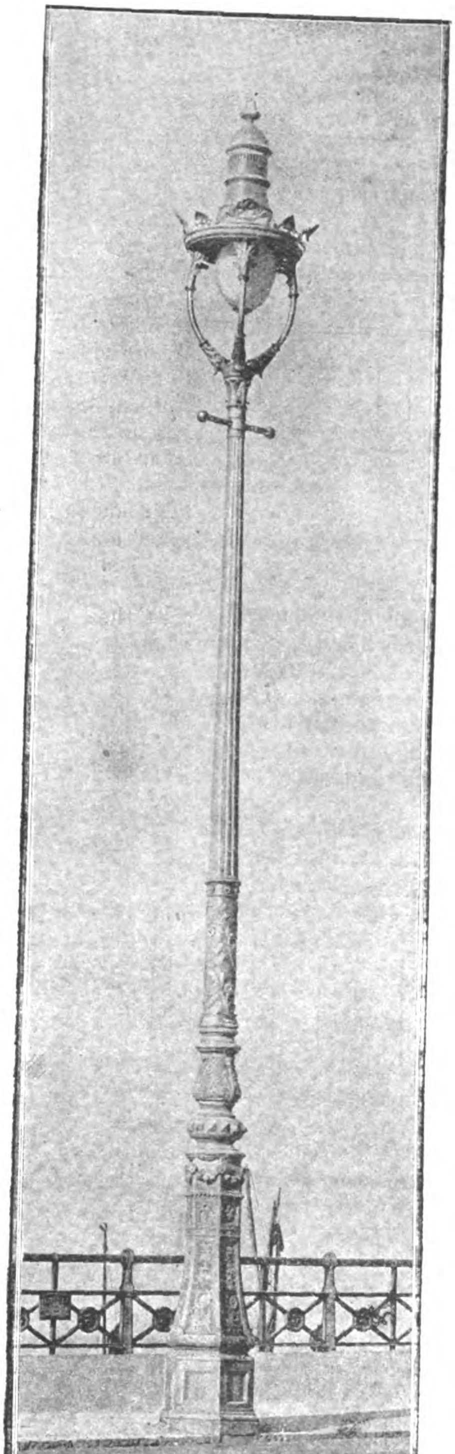

FIG. 1.

at present, none of the engines are condensing. The water is supplied to the boilers by means of direct-acting feed-pumps. The steam mains are of steel, 6in. and 7in. in diameter.

In the engine-room there are, at present, six direct coupled dynamos, driven by Willans engines. Four of these steam dynamos, namely, two large ones and two small ones, are ranged in a row across the width of the room; while the remaining two large steam dynamos form half of a row of four which

Digitized by Google

will be placed along the length of the engine-room. The two smaller engines are 2-crank compound non-condensing engines; and each of the smaller dynamos develop 300 amperes at 150 volts, running at 450 revolutions per minute. These dynamos are of the Goolden type, fitted with Latimer-Clark armatures. The two larger machines, which are in the same row with the small ones, are each capable of developing 400 amperes at 300 volts, running at 350 revolutions per minute; and they are of the above-named type. The two other large engines are 3-crank compound non-condensing Willans engines, each of 360 H.P., and they are direct coupled to Latimer-Clark dynamos. The tender of Messrs. Crompton and Co. has been recently accepted for the supply of plant for the two new 360 H.P. steam dynamos. The exhaust steam from all the engines is conveyed to the feed-heaters, and thence to the chimney, by a 12in. cast-iron exhaust main. In the extensions which are in contemplation it is intended to use evaporative condensers. The illustrations, Figs. 2 and 3, show a vertical section and plan of the station respectively.

Sub-stations, at present, do not form part of the Brighton system; but the generating station is equipped with a spacious and well-stocked accumulator room. Here, there are 141 E.P.S cells of the 96 L-plate type and size, and the duty of these cells is to enable the generating station to be shut down in the small hours of the morning, &c., when there is very little load, thus economising the items of labour and fuel. These cells are employed, as at some battery stations, for varying the feeding pressure.

Engineers claim that their especial language is scale drawings and diagrams; and, with a desire to encourage this wholesome belief of theirs, we have prepared a number of illustrations of the Brighton plant. Among these are Figs. 4 and 5, illustrating the switchboard, and we sincerely hope our readers will understand the language which they speak. One may draw a switchboard; one may design a switchboard; one may even make and erect and thereafter work a switchboard; but language fails when the attempt is made to describe a switchboard. Therefore are we glad that the engineer requires not ordinary language, and that he professes to see everything if only it is served up as a scale drawing. Fig. 4 is an elevation of the exterior of the main switchboard, and Fig. 5 shows its internal connections with the feeders, machines, and batteries. The set of middle or neutral wires of three-wire feeders is connected to the middle part of the switchboard, the two outers, the positive and negative sets of feeders, being connected on either side respectively. By means of screw plugs, which are put into tapped holes in the terminal bars before starting the machines, any one machine may be arranged to

feed any combination of feeders; and by means of quick-break switches, the ordinary connections or disconnections are made during the run. By this arrangement it is possible to group the feeders together in sets, and to transfer the sets or separate feeders from any one machine to any other at will. The index letters on the illustrations are explained in the notes which accompany them.

In the present network there are 16 feeding points. The feeders are of armoured cable, and have a normal current density of 1,200 amperes per square inch. The feeding points are at an average distance of 500 yards apart, and by the system of regulation which is adopted, a variation of not more than two volts occurs at any point in the network of distributors. In the daytime the pressure between the middle or neutral wire and the two outers is kept at 116 volts, and the pressure of the mid-points between the feeding points is not less than 114 volts. But in the evening, when the load comes on heavily, and when there would be a tendency to reduce the pressure at the mid points below 114 volts, the pressure at the feeding points is raised to 118 volts, thereby compensating for the increased drop in the distributors at high loads. It is found that this gives a much better regulation, as might be expected, than where the pressure at the feeding points is kept constant at all loads.

Great care has been exercised in the design of the three-wire network of distributors. From the exceptional information which Mr. Arthur Wright, the Corporation electrical engineer, is able to obtain through the use of his maximum demand indicator, a description of which we give below, it is possible to so arrange the local loads on each side of the neutral, as that very little current shall pass through the neutral wire. In fact, in many cases there is no return of current to the station, or flow from the station, by the middle wire; and this conductor acts merely as an inter-connection for the lamps. The streets in the area of supply are classified as "standard streets," "half-standard streets," &c., according to their probable demand; and the amount of copper laid down is based upon this system of estimation. A standard street is one which requires one ampere per yard run in the outer conductors.

The distributors once laid, great care is exercised in keeping them balanced. Again the demand indicator is the instrument which renders this possible. Each consumer is carefully checked as regards the variations of his demand throughout the year, and he even is honoured with a separate little load diagram indicating his doings; and the information obtained in this way enables the Corporation's electrical engineer to draw up a chart of the network, dotted over its surface with little circles containing two sets of numbers. The first number in each circle gives the mean of the currents in the two outer mains of the particular branch, and the second number gives the difference between the positive and negative outer currents, or the current in the balancing wire. Of course the new consumers are so placed as to tend to keep the latter number as near zero as possible.

We now come to the demand indicator, which merits some description, as it furnishes a correct means of ascertaining the actual call each consumer makes upon the generating plant of the central station. In order to understand the duty of this instrument it is necessary to describe the system of charging adopted by the Brighton Corporation, which is as follows:—7d. per unit is charged until the quantity consumed amounts to a use of the average maximum demand for 365 hours in half a year, which equals two hours per day, and all current consumed in excess of this quantity is charged at 3½d. per unit. The average maximum demand of each consumer is directly shown by the demand indicator being read once a month and the mean being taken as the consumer's actual demand. The Brighton instruments are calibrated to show directly the number of units to be consumed in the half-year before half price is charged instead of in amperes, as, at the Brighton voltage, each ampere used for two hours per day equals 42 units in the half-year. On this system the consumer is allowed a rebate directly his own load factor exceeds 8⅓ per cent. But the consumer is allowed to have a blaze of light occasionally, without fear of being betrayed by the faithful indicator. In order to prevent any single special demand for electricity raising the number of full-price units, the consumer may, in the event of his intending to burn a number of lamps in

FIG. 6.

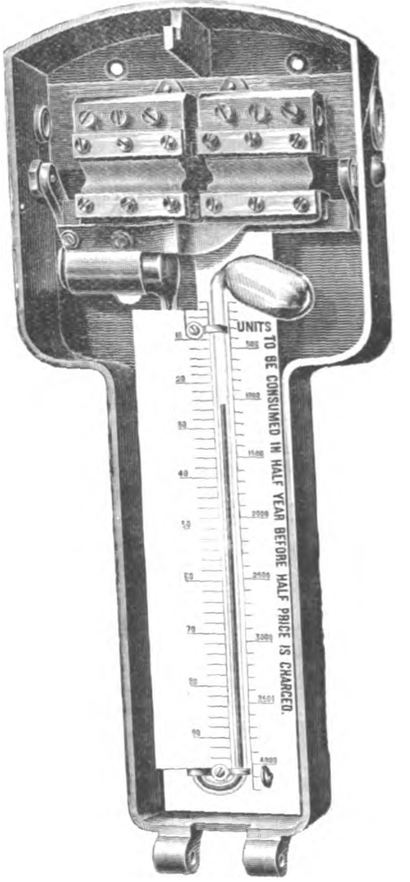

FIG. 7.

excess of his usual maximum on any such occasion not exceeding once in each month, give 24 hours' notice, in writing, of such intention to the Corporation, and they will thereupon short circuit the consumer's "demand-indicator" from registering the demand on the occasion so notified. Two views of this indicator are seen in the accompanying drawings; Fig. 6 shows the front exterior of the instrument, as it is placed in the consumer's house, and Fig. 7 shows the interior arrangements of the latest pattern. The current passes through a heating resistance coil which surrounds a sealed glass bulb, connected to which is a U-shaped tube filled with liquid, with a trap bulb at its further end. On current passing through this heating coil the air in this bulb is expanded and forces part of the liquid in the tube to overflow into the trap bulb where it remains until reset. When the current is cut off the air in the heating bulb naturally contracts, and the liquid in the tube therefore recedes, leaving a part proportional to the maximum current that has passed in the trap bulb, and displaying in the tube against the scale a shortened column of liquid similar to a thermometer. It will be seen that the lower the column of black liquid in the glass stem, the greater must be the number of full-price units consumed before the 50 per cent. rebate commences. The heat developed is, of course, proportional to the square of the current, but, owing to the cushioning due to the air in the receiver bulb, the volume of liquid spilled is practically proportional to the first power of the current.

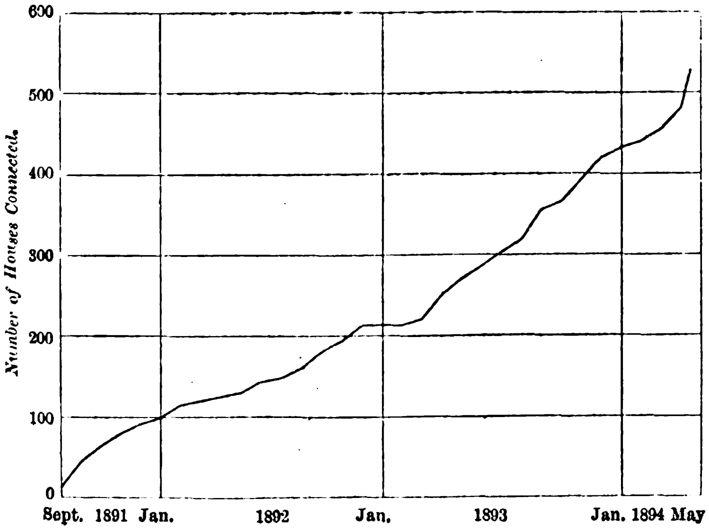

FIG. 8.

Great care is taken to calibrate every indicator, but the scales are almost exactly, if not quite uniform. The instruments are reset very easily, all that is necessary being to tilt the interior part, which is hinged for the purpose, until the liquid in the trap bulb flows back and refills the tube. The loss of pressure does not exceed half a volt even in the smallest instruments, and is quite inappreciable in the larger ones. The influence of this demand indicator upon the habits of the consumer is most salutary. Instead of burning a great many lamps at a time for short periods, he is induced to burn a normal number of lamps for long periods; thereby unconsciously flattening the station load diagram and filling out the work of the plant over an extended period. Mr. Wright informs us that the influence of this indicator has been most marked, and he reports that the station load factor is now 15 per cent. better than during last year. He also informs us that he has great hopes that the satisfactory result of the present year's working will enable the Corporation to reduce the number of hours each consumer has to use his demand from two hours to one hour per day, or in other words, to give every consumer whose load factor exceeds 4·17 a reduction proportional to the excess of his load factor above this figure. We are glad to be able to state that there are no signs either of lamp saturation or of saturation of the first differential coefficient between lamps and time, on the Brighton mains; and that although the load is thus increasing at an increasing rate, the hours per lamp are also on the ascending scale. The accompanying curve, Fig. 8, shows the rates of increase of the total number of houses wired, from September, 1891, to the present time.

Our thanks are due to Mr. Arthur Wright, the Corporation electrical engineer, for his kindness in supplying us with particulars and numerous drawings of the Brighton electric supply system, and for his courtesy in allowing us to explore the station.

SOME VOLTAIC COMBINATIONS WITH FUSED ELECTROLYTES AND GASEOUS DEPOLARISER.*

BY J. W. SWAN.

In this Paper are described several voltaic combinations in which fused electrolytes and a gaseous depolariser were used. The electrodes were the same in all the experiments, viz., lead in a fused state as the positive, and carbon as the negative. The electrolyte used in the first experiments was a fused mixture of KCl, NaCl, but this was changed for one of $PbCl_2$. The depolarising gas used in all the experiments was chlorine, and was so applied as to chemically act on the electrolytic products formed at the carbon pole. Several methods of applying the gas were employed—by forcing the gas through porous carbon, by making the carbon pole tubular, and feeding the chlorine through it, and by nearly wholly surrounding the carbon pole by an atmosphere of chlorine.

The condition found to be most necessary for successful depolarisation was *to alternately expose the carbon pole to the action of the gas and electrolyte in rapid succession.* During the electrolytic action, the lead dissolves as chloride of lead, and lead is deposited on the carbon pole, but is immediately reconverted to chloride by the action of the chlorine gas. The theoretical E.M.F. corresponding to the union of Pb and Cl_2 is 1·7942 volts, the highest obtained was 1·40 volts, this lower E.M.F. was probably due to the incomplete solution of the lead at the carbon electrode.

A noticeable feature of this kind of cell is the very low internal resistance, which makes it possible to obtain a large current density with comparatively small electrodes. In one of the experiments a current of 1·0 ampere was given with an area of the carbon of 10 to 12 sq. cm. It was also observed that the internal resistance, and at the same time the polarisation, *decrease*, when the electrical output *increases*, and that the cell gave an almost constant effect. The best results were obtained with small cells, the action of the chlorine being then more effective than when larger cells were employed. Experiments were also made with oxygen as a depolariser, but a description of them is left for a future Paper.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

TO-DAY (FRIDAY), June 1st.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Work of Hertz," by Prof. Oliver Lodge, F.R.S.

MONDAY, June 4th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

TUESDAY, June 5th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Modern Microscope; an Instrument for Recreation and Research," by the Rev. W. H. Dallinger, F.R.S.

FRIDAY, June 8th.

PHYSICAL SOCIETY.

5 p.m. (1) Discussion of the Paper by W. Bally and Prof. Ramsay "On the Relations of Pressure, Volume, and Temperature of Rarefied Gases;" (2) An Exhibition of Photographs of Flames by Capt. Abney.

ROYAL INSTITUTION.

9 p.m. Friday Evening Discourse: "The Newtonian Constant of Gravitation," by C. Vernon Boys, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electric Furnace.—In heating magnesia in the electric furnace, M. Moissan has noted a peculiar phenomenon, viz., that this material apparently contracts with heat, its specific gravity rising from 3·193 when cold up to 3·654 at a bright red heat.

CENTRAL STATION IDEALS.

The Paper on "The Cost of Electrical Energy," read before the Institution of Electrical Engineers, is the most important contribution that has been made to the proceedings of this body for some time. The first impression after reading it was that it would perhaps have been discussed in a manner more worthy of its contents before the Institution of Civil Engineers. But the discussion, though far from what it might have been had more supply-station men spoken, did fair justice to the Paper, and was a credit to the Institution. The point of the whole argument, namely, the setting up of a high ideal, and the careful examination of the losses which prevent its realisation, was recognised by a very small proportion of those who took part in the discussion. Even if this ideal should prove to be unattainable before the year 1994, this point does not lose its importance. More than one speaker not only completely failed to grasp the idea of comparison with an ideal, but neglected altogether the basis of 5,000,000 units per annum. In setting up a high ideal of this kind it is natural that the separate ideals of the components should be taken, but as Mr. M. ROBINSON pointed out, some of these are mutually exclusive, and as it is difficult to give weighted values to the different *desiderata*, the ideals must be purely theoretical. There is some satisfaction in this, for, as Mr. CROMPTON observed in his reply, we do not want any more MATTHIESSEN'S ideal coppers and 104 per cent. conductivities. Instead of directing their attention to the examination of the differences between the ideals and actual facts, most speakers tried to excuse their shortcomings, and to make out from this feeble point of view that Mr. CROMPTON was a wild enthusiast.

It is perhaps inevitable that the engineers of some supply companies should be reluctant to take part in such discussions. We cannot believe that the remarkable lack of such men on this occasion was due to the consciousness of the shortcomings of the systems with which they are concerned, but rather to apathy, and in some cases inability to make sufficiently careful measurements on which to base

Digitized by Google

their remarks. Not every station is equipped with water-meters, pyrometers, or convenient coal-weighing tackle, and it is to be feared that the electrical measuring instruments, especially in alternate-current stations, are sometimes lamentably inaccurate. So long as the pressure is kept fairly steady throughout the district, there is a tendency to neglect further measurements, and the total output is reckoned by adding up the records of the consumers' meters. Judging by our own experience in collecting statistics, Mr. CROMPTON was very fortunate, especially when the statistics were required for rigid analysis and comparison. From one quarter alone unamiable remarks and sneers were received, and these, unfortunately, in the course of the discussion, nor can the discourtesy be excused on the ground that no statistics of the working of the Chelsea Company have ever been published, with the exception of an utterly ridiculous test of the boilers.

The Paper and the discussion thereon were remarkable as the occasion of two announcements of conversion. The author, once an advocate of Lancashire boilers, now believes in Babcock-Wilcox boilers, and Mr. RAWORTH confesses the superiority of direct-driving over rope or belt-driving. The first of these conversions has been the outcome of long observation and careful experiment, and full, though not perhaps altogether convincing, reasons were given. The second came rather as a surprise. With the exception of ship-lighting plant, the Brush Company have, so far as we can remember, never, until the Bankside station was started, departed from the ancient and time-honoured flapping belts or flopping ropes, but Mr. RAWORTH announced that he had been waiting for an opportunity to do what nearly everybody else has been doing for years. It is true that there is a tendency to run alternators at a high speed, simply because ordinary frequencies cannot be obtained from machines of moderate output without the use of huge armatures, but this must be faced by advocates of alternate currents along with the other difficulties of their system. It is, at all events, satisfactory to learn that all rope-driving engineers are not running their heads against a wall, but that one of them, at least, has the frankness to say that "as soon as they could see their way to do it, they would abandon rope driving, and come to direct driving also." Among the contributions to the subject was the creation in the course of the discussion of the expression "antiquation factor" by Mr. HAMMOND. The idea thus embodied has long been recognised, and many a municipality has declined to entertain proposals for electric lighting because improvements are continually being made, and have argued that the hopeless antiquation of any plant that they might purchase would therefore be only a question of time. A man might as reasonably spend all his life in bed because, owing to the inevitable changes of fashion, any clothes he put on would some day be out of date. This factor is worthy of consideration, though there is nothing alarming in it, and the most important application that has, as yet, been experienced is the abandonment of house for sub-station transformers.

Prof. UNWIN's apology for taking part in the discussion, on the ground that he was only a mechanical engineer, reminds us that the chasm which once separated the electrician from the engineer has been steadily closing up, but there is an indication now and then that a chink yet remains. Some men will always be mechanical engineers, and get some one at three or four pounds a week to do the electrical part for them; others will always be mere electricians, and they will only succeed when they are sensible enough to seek assistance from mechanical men. Prof. UNWIN's remarks on superheating were of great interest, and only on one point was he out of touch with the subject of the Paper. Twenty-four-hour tests of boilers are of little or no use to men who have to deal with a load factor 15, and regard 20 as a happy ideal. Comparisons of boilers on different load factors are worse than useless. The same criticism applies to Mr. CROMPTON's Table IV. of the "Maximum Efficiency of Sundry Types of Boilers at Test Trials." The Babcock-Wilcox boiler is credited with an efficiency of 76·5 per cent. on the strength of a five hours' trial conducted by Prof. ROBINSON on a battery of five boilers, all of which were continuously and fully loaded. The figure for the marine boiler, however, is derived from a totally different kind of trial, and is given by Mr. CROMPTON as only 63 per cent. Mr. CROMPTON derives this low figure from a go-as-you-please two days' trial of the boilers at Glasgow, by Prof. KENNEDY. The boilers took the load as it came on; and, while the mean load during the trial was only 198·7 kilowatts, the maximum load was as high as 669·4 kilowatts. Mr. CROMPTON therefore offers for comparison a trial of the Babcock-Wilcox boiler on a purely ideal 100 per cent. load factor, and a trial of a marine boiler on no higher than 29·7 per cent. load factor. A good many engineers still believe that Lancashire boilers are yet in the running, and we are inclined to think that one reason why they are not pushed is that there are no important patents, and it is worth nobody's while to push them. A boiler patented in principle, patented in design, and patented in detail, pushed by a sole and exclusive agency, and a smart agent who will furnish working drawings of settings and flues, and throw in advice about steam pipes, or will on an occasion design a whole station from the coal store as far as the stop valves on the engines, saves consulting engineers so much trouble that it is sure to be popular. If it chance to be a good boiler, so much the better.

A METHOD FOR THE TREATMENT OF ROTATING OR ALTERNATING VECTORS, WITH AN APPLICATION TO ALTERNATE CURRENT MOTORS.

BY PROF. GALILEO FERRARIS.

(Continued from page 112.)

7 (*b*). *Alternating Vectors of Different Direction.*—If the two given alternating vectors, a and a', are not parallel, the general construction explained in Art. 5, and represented in Fig. 6, leads us to find that the two given vectors are equal to two vectors, one alternating, of fixed direction, represented by O A, and the other rotating, of constant value, represented by S″ S′. But we have particular cases in which of these two vectors there exists sometimes the one and sometimes the other. There exists only the alternating vector of fixed direction when the two component alternating vectors have the same phase.

In fact, in this case the angles O S S′, O D D′ (Fig. 8) are both equal to the supplement of the angle $a\,o\,a'$, and, besides, are equal to one another. Whence the triangles S O S′, D O D′, are equal to one another, and, in consequence, we have O S′ = O D′. Thence, as it was demonstrated [3], they give for resultant a simple alternating vector of fixed direction. This resultant is represented by the segment O A equal to 2 O S′ and to 2 O D′, and situated on the bisectrix O F of the angle S′ O D′. Its phase has the angular value $S'OA = \frac{1}{2} S'OD' = \frac{1}{2} s\,o\,d = \frac{1}{2} s'\,o\,d'$; that is equal to the phase of the component alternating vectors.

If you draw a A′ equal and parallel to $o\,a$ and draw o A′, you have the triangle $o\,a$ A′, which is similar to the triangle O S S′, because the angle a is equal to the angle S and the sides $o\,a$, a A′ are equal to twice the sides O S, S S′. Thence we have o A′ = 2 O S′ = O A.

Moreover, by the equation

$$\widehat{a\,o\,A'} = \widehat{SOS'},\ \widehat{S'OA} = \frac{1}{2} S'OD' = \frac{1}{2} \widehat{s\,o\,d} = \widehat{s\,o\,a}$$

we deduce $s\,o$ A′ = S O A; which signifies that o A′ is parallel to O A. In consequence o A′ is equal and parallel to the resultant vector O A. We may say therefore: Two alternating vectors of equal phase are compounded into a single alternating vector of equal

Digitized by Google

phase, of which the amplitude and the direction are represented by the diagonal of the parallelogram made on the straight lines which represent by amplitude and by direction the two component vectors.

8. The composition of two alternating vectors gives, however, as resultant a simple rotating vector when one or other of the rotating vectors O D′, O S′ (Fig. 6, Art. 5) is equal to zero. This case is proved when $o\,s$ and $o'\,s'$ (Fig. 6) or $o\,d$ and $o'\,d'$ have equal magnitudes and opposite directions; then in fact the point S′, or the point D′ coincide with O. The condition $o\,s = o'\,s'$ or $o\,d = o'\,d'$ implies that it may be $o\,a = o'\,a'$ or that the amplitudes of the two given alternating vectors may be equal to one another.

The condition, then, that $o\,s$ and $o'\,s'$ or $o\,d$ and $o'\,d'$ have opposite directions implies a relation between the direction of the two alternating vectors $o\,a$ and $o'\,a'$ and the phases of the same. It is easy to see what these relations are. Let us suppose in fact that $o\,d'$ is opposite to $o\,d$. We call the angle $a\,o\,a'$ between the directions

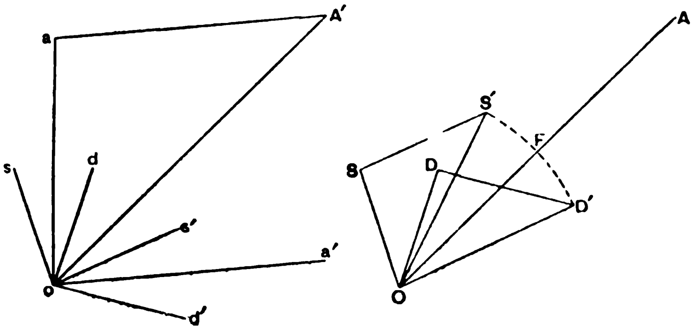

Fig. 8.

of two component alternating vectors, and we represent by ϕ and by ϕ' the angular values $a\,o\,d$, $a'\,o\,d'$ of the phases of the same vectors; we have

$$a + \phi' - \phi = \pi, \text{ or } \phi' - \phi = \pi - a.$$

Thence two alternating vectors of fixed directions give for resultant a simple rotating vector, when they have equal magnitudes and present a difference of phase, the angular value of which is equal to the supplement of the angle comprised between their respective directions.

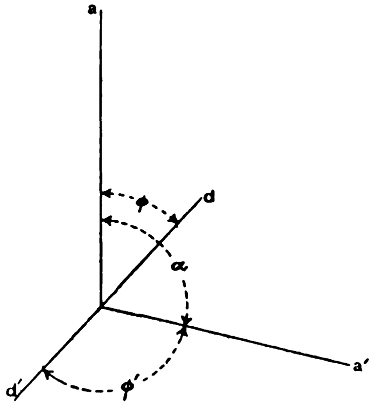

Fig. 9.

9. *Examples.*—As first example, let us consider the case of two alternating vectors, mutually perpendicular $o\,a$, $o'\,a'$ (Fig. 10). The theorem states that, in order that they may be compounded into a simple rotating vector, there should be in the first place $o'\,a' = o\,a$. In the second place, there should be $\phi' = \phi = \pi - a$, and thence being

$$a = \frac{\pi}{2}, \quad \phi' - \phi = \frac{\pi}{2}.$$

If, for example, we take $\phi = 0$ or the angle $o\,a\,d' = 0$, there should be $\phi' = \frac{\pi}{2}$, or the angle $a'\,o'\,d' = \frac{\pi}{2}$.

Now, with these conditions given, that the two vectors a and a' do truly produce as resultant a rotating vector is recognised at once on applying to them the construction of Art. 5, Fig. 6. In fact, to compound d with d' we must draw $O\,D = o\,d$, and then $D\,D' = o'\,d'$, with which it falls again on point O; to compound instead s with s' you have to draw O S and S S′ equal and parallel to $o\,s$ and to $o'\,s'$, by which we find the resultant O S′, which is a left-handed rotation of magnitude equal to $s + s'$, or to $2\,s$, or to a and to a'. The two given alternating vectors produce then as resultant a simple rotating vector of the same frequency and of magnitude equal to their amplitude.

As a second example, let us consider the case of two equal alternating vectors, $o\,a$ and $o'\,a'$ (Fig. 11), the direction of which comprises an angle, $a = \frac{3}{4}\pi$.

In this case the condition expressed by the theorem above demonstrated is that we have $\phi' - \phi = \frac{\pi}{4}$.

If, for example, $\phi' = \widehat{a\,o\,d} = 0$, there should be $\phi' = \widehat{a'o'd'} = \frac{\pi}{4}$. And, indeed, if we apply to this case the construction of Fig. 6 we find that D′ coincides with O. The resultant is reduced to the rotating vector O S′. Its magnitude is represented by the hypotenuse of the isosceles rectangular triangle O S S′; it is, therefore, equal to $s\sqrt{2}$ or to $\frac{a}{\sqrt{2}}$.

10. From the case already considered of only two alternating component vectors, we pass at once to the general case of any

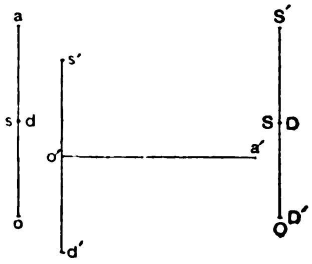

Fig. 10.

number of vectors: Any system of alternating vectors can be equivalent to a simple rotating vector. The necessary condition why that should happen is simply this—that the polygon of the components d, or that of the components s, should be a closed polygon.

An important particular case is that in which the component vectors are equal, and make with one another equal angles. Let there be given in one plane, N, equal alternating vectors, each of which makes with the preceding an angle a, which is neither π nor a multiple of π, and has relatively to the same a lead in phase of angular value equal also to a. Then each of the rotating vectors s makes with the preceding an angle $a - a$, or zero. The polygon of the s vectors has all its sides on the same straight line; the resultant S of all the s vectors is equal to their sum, or $S = N\,s$. The polygon of the d vectors is, on the other hand, a regular polygon, of which the external angles have the value $2\,a$; in order

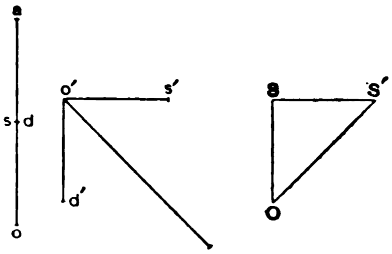

Fig. 11.

that this may be closed it is necessary and sufficient that N of such angles should make a multiple of four right angles, or that we have

$$2\,a\,N = 2\,k\,\pi$$

or

$$a = \frac{k\,\pi}{N},$$

where k is any whole number not divisible by N. If that condition holds good, the N rotating vectors d have a resultant nul; that is to say, that the N given alternating vectors have for resultant the simple rotating vector S. If we call a the common amplitude of the given alternating vectors, the value of the rotating vector becomes

$$S = N\,s = \frac{N}{2}\,a.$$

If instead of supposing, as we have done, that each of the given vectors has a lead in phase a relative to that which precedes it, we might have supposed that it has a lag in phase, we should have found that the polygon of the d vector stands upon a straight line, and gives $D = n\,d$, and that the polygon of the s vectors is closed and gives $S = O$; in this case the resultant of the N given alternating vectors would be a simple vector, D, rotating towards the right. We have excluded the case of a equal to π, or to a

Digitized by Google

multiple of π; and, in consequence, we have said that the whole number k should not be divisible by N. If we made $a=\pi$ or to a multiple of π or if we took k equal to N, or to a multiple of N, the external angles of the polygon of d will be equal to 2π or to a multiple of 2π, and the polygon would reduce like that of s, to a straight line. In that case we should have two rotating vectors S and D both equal to $\frac{N}{2}a$ and of opposite senses, which would give as resultant an alternating vector of fixed direction and of amplitude equal to N a. Which is what was known before, because to suppose $a=\pi$ or a multiple of π is equivalent to supposing that the given alternating vectors are parallel to one another. The cases which most commonly have to be considered in the study of electric motors are those in which $k=2$, those moreover in which the considered alternating vectors are regularly distributed, at an equal angular distance all around an axis. Among these cases, then, special mention is required where N=3. Then the angular distances between the given vectors, and the angular values of their difference of phase, are equal to $\frac{2}{3}\pi$, or are of 120deg. The rotating vector, which results from the compounding of the three alternating vectors has the value $\frac{3}{2}a$, or is equal to one and a-half times the amplitude of each of the component vectors.

11. That which precedes concerns the composition, or the sum of vectors considered by us. For the application to those we are considering, it is suitable to add some considerations respecting the products $a\,b\cos\phi$, $a\,b\sin\phi$ of the amplitudes a and b of two vectors by the cosine or the sine of the angle ϕ comprised between the directions of the same;—products of which the first is the scalar with changed sign, and the second is the tensor of the vector of the product of the two vectors.

In the first place it is suitable to set down the following proposition: let there be given two groups of vectors, and at a given moment let there be: a the magnitude of any one of the vectors of the first group, b that of any one of the vectors of the second group, A the momentary value of the resulting vector of all the vectors a, B that of the resultant of the vectors b, ϕ the angle comprised by one vector a and one vector b, and Φ the angle of A with B, we have

$$\Sigma\, a\, b\cos\phi = \mathrm{A\,B}\cos\Phi,$$
$$\Sigma\, a\, b\sin\phi = \mathrm{A\,B}\sin\Phi.$$

In order to demonstrate the first of these equations, already well known, it is sufficient to observe that if we call Ψ the angle between A and one of the vectors b, we have

$$b\,\Sigma\, a\cos\phi = b\,\mathrm{A}\cos\Psi,$$

whence $\Sigma\, a\, b\cos\phi = \Sigma\, b\,\mathrm{A}\cos\Psi = \mathrm{A}\,\Sigma\, b\cos\Psi.$

But $\Sigma\, b\cos\Psi \mathrm{B}\cos\Phi,$

thence, $\Sigma\, a\, b\cos\phi = \mathrm{A\,B}\cos\Phi.$

The second equation, or the $\Sigma\, a\, b\sin\phi = \mathrm{A\,B}\sin\Phi$, is demonstrated in an analogous manner.

12. In the second place it is convenient to see what are the mean values of the products $a\,b\cos\phi$ and $a\,b\sin\phi$, when the vectors a b are of the kind which we were considering here—that is, when they are rotating vectors or alternating vectors. And here we have several cases.

First Case.—If the two vectors a and b are vectors rotating in the same plane, with the same frequency and in the same sense, the angle ϕ made by the same remains constant; that is, equal to the angular value of the difference of phase of two vectors. Thus, by the definition of a rotating vector adopted by us, both a and b are constant, so the products $a\,b\cos\phi$, $a\,b\sin\phi$ are independent of time.

Second Case.—If a and b are still vectors rotating in the same plane, but with different frequency n and m, the angle ϕ made by them passes in every unit of time $n-m$ times from 0 to 2π, or varies between 0 and 2π in the time $\frac{1}{n-m}$. The mean value of $\cos\phi$ and of $\sin\phi$ during such time is equal to zero, and besides the mean value of the considered products is also equal to zero.

Third Case.—A particular case included in that just now considered is that of two vectors rotating in opposite senses: if the frequencies of the two rotating vectors are n and m, the angle ϕ varies between 0 and 2π in the time $\frac{1}{n+m}$, and during this time the mean values of $a\,b\cos\phi$ and of $a\,b\sin\phi$ are equal to zero.

Fourth Case.—Another particular case is that in which a is a rotating vector and b a fixed vector of constant magnitude. This case can be reduced to the preceding, making simply $m=0$. Also in this case the mean products equal zero.

Fifth Case.—If a is an alternating vector of fixed direction and b is a rotatory vector, we can imagine a decomposed into two equal vectors rotating in opposite directions d and s, and making use of the theory recorded in the preceding article (11), put

$$a\,b\cos\phi = d\,.\,b\cos\delta + s\,b\cos\sigma,$$
$$a\,b\sin\phi = d\,.\,b\sin\delta + s\,b\sin\sigma,$$

where δ and σ represent the angles which at that moment of time b makes with d and with s. So we are led back to the preceding cases. If a and b have different frequency, so the products $d\,b\cos\delta$, $d\,b\sin\delta$, also the products $s\,b\cos\sigma$, $s\,b\sin\sigma$, have mean values equal to zero; whence also the means of $a\,b\cos\phi$, and of $a\,b\sin\phi$, are equal to zero. If a and b have a similar frequency, only the products $d\,b\cos\delta$, $d\,b\sin\delta$, or only $s\,b\cos\sigma$, $s\,b\,\sigma$ are zero; the other two are different from zero, and are constant.

If, for example, b is a vector rotating right-handedly, the products $s\,b\cos\sigma$ $s\,b\sin\sigma$ have a mean value equal to zero, and the products $d\,b\cos\delta$, $d\,b\sin\delta$ are constant. We have, therefore, simply

$$\text{mean of } a\,b\cos\phi = d\,b\cos\delta$$
$$\text{mean of } a\,b\sin\phi = d\,b\sin\delta.$$

If we represent by A the amplitude of the alternating vector, we have $d=\frac{\mathrm{A}}{2}$, and whence

$$\text{mean of } a\,b\cos\phi = \frac{1}{2}\mathrm{A}\,b\cos\sigma,$$
$$\text{mean of } a\,b\sin\phi = \frac{1}{2}\mathrm{A}\,b\sin\delta.$$

If we take as the origin of time the moment at which a has the maximum value A, the angle δ which figures in these expressions is the angular value of the difference of phase between a and b.

Sixth Case.—If, finally, a and b are two alternating vectors of equal frequency, we may consider the first as resultant of two rotating vectors d and s, and the second as resultant of two other rotating vectors d' and s'. By virtue of the proposition demonstrated in Art. 11, the products $a\,b\cos\phi$, $a\,b\sin\phi$ are at any moment equal to the sum of those which we have with the combinations $d\,d'$, $d\,s'$, $s\,d'$, $s\,s'$. But by virtue of that which was given before in treating Case 3, the mean values of the products corresponding to the second and to the third combination are equal to zero; thence, we call δ the constant angle between d and d', and σ the constant angle between s and s', we have:

$$\text{mean of } a\,b\cos\phi = d\,d'\cos\delta + s\,s'\cos\sigma,$$
$$\text{mean of } a\,b\sin\phi = d\,d'\sin\delta + s\,s'\sin\sigma.$$

If we call A and B the amplitudes of the two given alternating vectors, and if we note that

$$d=s=\frac{\mathrm{A}}{2}, \text{ and } d'=s'=\frac{\mathrm{B}}{2},$$

we may be able to write thus:—

$$\text{Mean } a\,b\cos\phi = \frac{\mathrm{A\,B}}{4}(\cos\delta+\cos\sigma),$$

and

$$\text{mean } a\,b\sin\phi = \frac{\mathrm{A\,B}}{4}(\sin\delta+\sin\sigma).$$

Then if, calling α and β the phases of a and b, we note that

$$\delta=\phi+\beta-\alpha, \text{ and } \sigma=\phi-\beta+\alpha,$$

we may write again:

$$\text{mean } a\,b\cos\phi = \frac{\mathrm{A\,B}}{2}\cos\phi\,.\cos(\beta-\alpha),$$
$$\text{mean } a\,b\sin\phi = \frac{\mathrm{A\,B}}{2}\sin\phi\,.\cos(\beta-\alpha),$$

(To be continued.)

COST OF ELECTRICAL ENERGY.

At the ordinary general meeting of the Institution of Electrical Engineers, held on Thursday evening, May 24th, Mr. Alexander Siemens, President, in the Chair, the discussion on Mr. Crompton's Paper on the "Cost of Electrical Energy," was concluded. An asterisk denotes that the speakers have returned the abstracts of their remarks revised:—

*Mr. E. C. DE SEGUNDO said as so many had spoken on the essentially practical details, he would confine himself to analysing Mr. Crompton's theories. In considering efficiency in a subject of this sort he thought it was wiser, in order that they might know exactly where they were, to compare the efficiencies with the best possible rather than with the absolute efficiency. Now, Mr. Crompton assumed in his ideal that boilers could be made which would evaporate 12lb. of water at 150lb. pressure per square inch per pound of fuel. That would correspond to an absolute efficiency, assuming a calorific value of 14,500 B.T.U. of 86 per cent. But a boiler could not do more than it possibly could do, and if they took into consideration the minimum amount of air which must be allowed to go into the furnace in order to complete combustion, and assumed

Digitized by Google

an average temperature for the products of combustion, some 915 thermal units would be carried away and there would be left a maximum possible evaporation of 13·2lb. of water at 150lb. pressure. Mr. Crompton's estimate of 12lb. therefore meant a relative efficiency of 91 per cent. But it was not always possible to regulate the supply so that only the exact amount really necessary for the complete combustion of the coal was introduced; assuming they admitted 18lb. of air per lb. of coal consumed, the possible maximum was reduced from 13·2 to 12·6lb. of water at 150lb. pressure. Therefore Mr. Crompton's assumption of 12lb. really meant a relative efficiency of 95 per cent. With regard to the engines, Mr. Crompton said condensing steam engines could and would be made which would give them 1 I.H.P. hour per 13lb. of steam at from half to three-quarter load. This assumption amounted to a 19 per cent. heat efficiency. From calculations based on actual practice, he found that 10 per cent. was about the outside absolute efficiency one could count upon for high-pressure non-condensing steam dynamos. The next point he thought worthy of a little consideration was this: People did not care a bit how many watts were used for lamps; they did not buy watts, they only considered candle-power, and when they considered the marvellous efficiencies that had been obtained in the various units in their generating stations, they could not hope for much improvement in boilers or dynamos or engines; but there was room for a great deal of improvement in the distributing system, and above all in the lamps. It was obvious that if incandescent lamps could be made so that they would give 1 c.p. for 2½ watts with the same life and percentage loss of candle-power as they did now, it would be equivalent to bringing the price down to about 3¾d. per unit, as far as the consumer was concerned.

*Mr. J. N. SHOOLBRED said he could not follow Mr. Crompton when he said that Lancashire boilers seemed to produce rather worse results than the water-tube. In the water-tube, there should be taken into consideration the question of the result of the extinction of the fires and the cooling down of the brickwork and connections and the other losses which arose therefrom. With regard to the question brought out in Table VI. of the relative economy of the various systems of "converted alternating," "converted continuous," and "direct continuous," Mr. Crompton drew attention among other things to the economy derived from "storage." He (the speaker), by the courtesy of the Bradford Corporation, had been able to place a number of diagrams on the wall which showed what was the actual visible economical effect of storage batteries on the working of the Bradford station for four years. All of these diagrams showed that there was an appreciable period in the 24 hours, amounting, even in winter, to some eight hours, during which the engines were shut down. The members could not close their eyes to the fact that a considerable economy must arise from the relief granted to the engines and the saving of time, wages, and so forth; and that any system that required the engines to run during the entire 24 hours must necessarily be more expensive in itself than the above with storage. He had been enabled likewise to place on the wall diagrams showing the financial working of the Bradford station for the last four years; and indicating proportions of expenditure to receipts. Mr. Geipel, in his remarks, seemed to say, speaking of the proportion of capital per unit sold, that Mr. Crompton's suggested 2s. was almost an impossible figure, especially for continuous current installations. The result of the working of the station at Bradford had been that during the whole of 1893, the proportion of capital had only been 2s. 6d. per unit sold, and there was good reason to suppose that 2s. might be reached before long. Mr. Hammond also said if 2s. ever was reached, it would require a great many units to be sold. Last year, the figure he had named was attained with slightly under half a-million units.

Mr. HENWOOD said Mr. Crompton had spoken of 2½lb. of coal per indicated horse-power hour being the ordinary work done in 1883. Of course he was perfectly well aware that during the last ten years the consumption of coal in marine boilers had been reduced to 1·7lb. for triple expansion engines. With so poor a fuel as coal there were inevitable losses by ash. Moreover, the system of manual firing was unscientific, and ought to be discarded. Mr. Crompton had expressed the opinion that mechanical firing was still more wasteful and inefficient, and he (Mr. Henwood) concurred. Mr. Crompton also remarked on the heating of the fire bars; even with the ordinary cast-iron fire bars they were often burnt out. A method had been tried of using tubes filled with water as fire bars. He quite concurred with the author's view that it was best to use nothing but the coals of highest calorific values. He was glad to find the author speak so well of the Babcock boiler, and stating that it could be forced without priming. He (the speaker) wished to place it on record that in his judgment it was an utter loss to attempt to use coal when burning oil, because it would not add anything to the effect, but would rather diminish the heat they did obtain from the oil. In a properly-constructed furnace for burning oil fuel the conditions were different from those which obtained when they wanted to burn coal. In the oil fuel furnace they needed to have the admission of air strictly under control, and not to allow a large accession of air to be thrown into the furnace, as was the custom when they were firing with coal; and, moreover, with an oil fuel furnace, they entirely avoided the loss and nuisance occasioned by the constant feeding of the fire. He would ask them not be too incredulous when he told them that with a reliable system of firing with oil there was an evaporation of over three times that obtained by coal.

*Mr. A. H. DYKES said the figures Mr. Crompton had put before them were of the utmost value in enabling them to judge of the value of different system and different pieces of apparatus; but it was important before they compared different systems or different types of engines on the basis of those figures that they should understand any conditions that modified the general result, and he therefore had pleasure in reading a letter from Mr. Tonge, engineer of the Preston Company, in which he gave a few details concerning that station. He did this because in Mr. Crompton's Paper this was the only low-tension station in which double-acting engines were used, and it would appear from that that the comparatively low efficiency of that station might be due to the particular type of engines or the particular system in use. After reading Mr. Tonge's letter, the speaker said it would be evident, on inspection of the figures, that the cost of coal was very largely affected by the strike of last year. It was peculiar that in the North, where coal was very low in value, only costing before the strike 6s. 3d. or 6s. 6d. instead of 20s. or so, they were affected by the strike considerable more than in the South, the cost of coal being nearly doubled. The actual water consumption had been found in practice to be 27lb. per electrical horse-power hour, and the coal consumption per unit sold was 29lb., the coal being small slack burnt in Lancashire boilers. The best consumption of coal for a period of over three weeks in winter was 17¼lb.

*Prof. W. C. UNWIN urged as an excuse for the appearance of a mechanical engineer in the discussion the fact that Mr. Crompton had shown in his Paper how large a part mechanical engineering played in at least the finance of central-station working. Mr. Crompton made some rather strong statements about the relative value of Welsh coal and coal of any other description. He admitted that in calorimeter tests North Country coal was nearly as good as Welsh coal. But Mr. Crompton said there was some difficulty in burning the hydro-carbons of the Northern coal, and that this made it practically much less valuable. A long series of tests was carried out between 1860 and 1870, partly for the Admiralty and partly for other people, the general result of which was that there was practically no difference between Northern coal and Welsh coal. It was smokelessness not calorific value which gave Welsh coal its great market value. Mr. Crompton said that a Lancashire boiler was only half a boiler, and that one had to put an economiser on to it before one made it a whole boiler. There were a good many tests which could be pointed to traversing that statement, but he would only quote one. Two or three years ago he had to carry out some tests of Cornish boilers, which, after all, were only Lancashire boilers with one flue. The boilers were not new, but were taken in the ordinary course of their use. Those boiler tests with Cornish-Lancashire boilers gave an evaporation of 11·87lb., but they were only half boilers without economisers. He (the speaker) believed the Babcock boiler was an excellent one, as good as any made, but in the paper it was especially praised because it would stand forcing. All he would say about that was that Mr. Crompton did not give them a single fact to enable them to judge whether it would or not. He said it was nominally rated at so much, and that it had been worked at 50 per cent. above that. He had not told them what the evaporation was per square foot of its heating surface. A comparison had been drawn between short stroke high speed engines and what Mr. Crompton called long stroke low speed engines. There were four methods of reducing cylinder condensation. They might reduce it 20 per cent. by steam jacketing, 20 per cent. by superheating, 20 per cent. by high speed, and 20 per cent. by multiple stage expansion. Which was the right one to adopt? As Mr. Robinson fairly and frankly said at the last meeting, up to the present it was the long stroke slow-speed enginees which had given the highest economical results, and that required to be borne in mind along with the statements about the necessity of high speed and short stroke. Mr. Crompton had given a formula for station arrangement something like this: Welsh coal, Babock boilers, high speed, short-stroke direct coupling. It was an excellent formula, but he did not think it was the only good one. Every central station designed had to be considered according to its circumstances. Mr. Crompton had very rightly looked to superheating as a method which would in the future have to be adopted in securing further economy in the working of steam engines. He (Prof. Unwin) objected to its being considered as a remedy for steam-pipe condensation, which he thought must be combatted in other ways. It had the more important function of reducing cylinder condensation. In speaking of superheating, Mr. Crompton told them that 20 or 25 years ago, when it was first used, it was easy to adopt superheating, but now it was difficult because steam was now of very much higher pressure; he said, with steam at 375deg. "any further superheating is very much in the nature of passing this steam through pipes at a temperature which nearly amounts to red heat, so that it is little wonder that not many engineers have cared about tackling such a difficult and risky problem." There had been in Alsace for the last 40 years one of the best schools of steam engineering. A year or two ago he (Prof. Unwin) had an opportunity of testing an engine there using superheated steam. He was not exaggerating when he said that there were now many hundred engines working with steam up to 100 or 120lb. pressure which were worked with superheated steam. He tested an engine of 500 H.P., constructed only about four years before, with separate admission and exhaust valves; as good a compound engine, as he supposed, could easily be found, having steam-jackets and every appliance for economising steam. He ran the engine for three days, two days with superheat, and one without, obtaining an economy of 20 per cent. in coal and 20 per cent. in steam, when the superheated steam was used. The steamchest of the engine was at a temperature of 520deg. F., and the engine had been working at that for two years without the cylinder covers being taken off. The fact was, there were difficulties about using superheated steam in modern days, but some of the difficulties which were put forward were not difficulties at all, and some of the difficulties which really existed were not sufficiently appreciated. The one difficulty that was always put forth was that with steam of this high temperature they would destroy their engine cylinder. He believed that was an absolute fallacy. In this engine, with the steam entering the steam chest at 520deg., there was no superheat inside the cylinder, the whole being expended in preventing initial condensation. He admitted that in Alsace they had a rather favourable case for using superheaters. Elephant boilers were largely used, and they dug a pit beneath the boiler and put the superheater down below; they had exceedingly little difficulty under those conditions. As far as he could learn, and he went through many mills, the stokers paid absolutely no attention to the superheaters, and did not even know whether they were on or off. Now, in the old days, when superheating was first introduced and always gave

Digitized by Google

a considerable increase of efficiency, he thought two very serious mistakes were made. At that time they invariably placed the superheater in the coldest part of the boiler tubes, in the up-take, or in some part where the gases left the boiler, and then the superheater was cumbrous and unsafe. If they had steam at a high temperature, and were going to superheat, then it was of no use putting the superheater in the coldest part of the flues, where they had not temperature enough to do the work : to use the superheater effectively they must put it somewhere where the gases were of high temperature, and in Alsace they put it immediately behind the bridge. If they put it in a cold part of the flues, they must have an enormously large and therefore dangerous superheater, but if they put it behind the bridge they might use a small and safe superheater. It must be assumed that the superheater would stand all the chances of daily work. If it was to do that it must sometimes, no doubt, approach the temperature of red heat, but he did not think it ever reached it. He thought, but was not sure, that that would exclude them from using a ductile material like mild steel in constructing the superheater ; at any rate, the superheater must be so constructed that it was practically a solid metallic construction without any jointing at all. Unless they could get that he did not think the superheater would remain without being gradually destroyed. There were problems still, no doubt, to be worked out, but he thought the fact that superheating had been so largely used in Alsace, and that wherever used it had shown economies ranging from 10 to 20 per cent., and that in good, new compound engines, was very encouraging.

Mr. PEACH said one boiler mentioned in the Paper was the "Economic," and in Mr. Paxman's absence he would like to make one or two remarks concerning it. The author had mentioned a good many good points of the boiler, but there was one recent improvement which he would like to point out. The tubes were divided into two groups ; they were close together at the back end of the boiler, and separated at the front end of the boiler by a space large enough to enable a man to get in, and there was also a space at the two sides of the back end of the boiler. That arrangement enabled the boiler to be entirely opened to internal examination for boiler inspection purposes, an advantage not shared by locomotive or marine boilers. One other point of big importance in the "Economic" boiler was the combustion chamber at the back, which when heated to a high temperature efficiently provided for the consumption of otherwise unconsumed products, and enabled inferior coal to be used without producing smoke. In the selection of a boiler one very important point was the cost for maintenance and repairs. There was only one instance given in the paper, that of the Kensington and Knightsbridge station, and the figure given there for the last four years' working seemed, on the face of it, rather high.

Prof. A. B. W. KENNEDY, taking the matter of coal first, said he was very pleased to inform Mr. de Segundo that Mr. Grimshaw, at the Eccleston-place Station, had got down to 4¼lb. per unit generated for three months last year. He would just show how he thought they might, perhaps, make a more possible ideal than the noble one he had put before them. If they took the actual working time they could evaporate 10½lb. of steam from and at 212°F., 8½lb. getting to the engines. Working that out on the basis of 16lb. of water per indicated horse-power hour for the 77 per cent. efficiency between the engine and dynamo at three-quarter load, and taking 90 per cent. of the units generated as sold, they got, as a result, down to 3·64lb. of coal per unit sold, or about 3¼lb. per unit generated. He would like, as a matter of his own opinion, to modify that of Prof. Unwin by saying that he believed it was more difficult to get the value out of North country coal, although certainly with proper care the value could be got out of it. As to boilers, it might interest members if he mentioned that in Glasgow they would stand nothing whatever but marine types pure and simple : they used, of course, the cheapest kind of fuel they could get, a kind of char, an inferior type of coke from the gasworks, which cost 4s. 6d. at the gasworks and was certainly not worth more. That worked very well in the marine types if not stirred up too much, and with a very economical result in money, and a very fair result in evaporation. He ought to say with regard to the calorific value of that coke, which Mr. Crompton had given in Table IX., that it should be marked approximate. He could not say that in the trial quoted it had a value of 12,000 thermal units. He would not add more than a word or two to what Prof. Unwin had said about the Lancashire boiler. He had not got any such excellent trials as Prof. Unwin brought before them, a couple of 24-hour trials, but on one particular trial, lasting, he believed, 10 hours, made on a plant of Aston and Dawson at Paddington, in 1890, they did get for a particularly careful test an evaporation of 11·7lb. per lb. of carbon burnt without economisers and 12·4 with a very high result. Of course the boilers were underworked, only burning 6lb. of coal per square foot of grate. Mr. Crompton had referred to the fact that certain figures were unknown to the works engineers themselves. He (Prof. Kennedy) felt sure that they would find it pay them to set to work to measure everything they were doing. It was possible now to get, if not the extremest accuracy, at least as much accuracy as they observed in measuring their coal. With regard to the question of rope-driving, it might interest members to know that there were being conducted just now in Belgium, under the care of a large committee of Belgian engineers, a series of what he hoped would be exhaustive and complete trials with this particular matter ; that was to say, plant had been set up for the particular purpose of measuring the amount of power taken up by belts and ropes as apart from the power actually taken to drive an engine and do its work. Mr. Crompton had referred to a method of getting an accurate report of the engine load factor of the day. He thought that was in the power of all of them with extremely little measurement, if the output of each engine was metred, and the number of hours that engine had run was also noted, they had the load factor of the engine for the day, sufficient for all practical purposes. He got that done as a regular matter week in and week out, so that they always knew the load factor of an engine during the hours it was worked. It was a most valuable thing to know. Then there were those "obscure losses," with which he was sorry to say his name was connected. The measurements were got by running all the water that got condensed in the steam pipes out into the sump and pumping it out and weighing it. Running with light loads quite lately he had found it amount to more that 8 per cent. of the whole, and in other cases it was 5 per cent. and 6 per cent. It was not so high proportionally in the winter, but it was a very serious matter indeed, as anyone who took the trouble to measure it would find. He hoped Mr. Crompton did not mean by his paragraph on slip 13 of the Paper that he really doubted whether there would be any economy due to condensation. Although they might not care to put a positive figure to the actual amount of economy, he thought most of them who had tried it were convinced that there was economy in the use of condensation. He thought in many cases it might amount to 12 to 15 per cent., or something of that kind. Upon the point of wages and superintendence in works, he thought there was a little misunderstanding sometimes as to the effect of size of works on its cost. The cost of works, as everybody present knew perfectly well, was divided into two parts, the actual cost of generating at the works and a series of outside costs. Now, there were certain points in which a small station had a great advantage over a large one. A small station might run with very little superintendence and very small office expenses, and as a matter of fact the actual cost of generation, as anybody knew who knew the details of works throughout the whole of the country, was sometimes as little at an absurdly small station as it was at a very big one ; but the total cost of the large one might be considerably smaller because of the items of interest on plant and other items which came in to reduce the cost at the big stations. However, when they came up, at a very rough approximation, to about 3,000 H.P., possibly 4,000 H.P., in the station, they had got to a point beyond which practically they were not going to reduce anything in their cost per unit. They would find the actual cost would be very much the same whether their larger power was put into two stations or one, and whether one or two was preferable would depend upon other considerations. It might be more convenient to have one, but it would not make any particular reduction in the cost per unit.

*Mr. DE SEGUNDO explained that his estimate of 4½lb. was per Board of Trade unit paid for by the consumer. The corresponding figure per unit generated would have been 3½ to 3⅞lb.

*Mr. DRUITT HALPIN said the first point he would remark on was the statement by Mr. Crompton that he considered the small and dust fuels only less valuable because part was liable to fall through the bars. They were all aware of the mechanical disadvantage of using fuel under those conditions, but he though one very great source of loss in that fuel which was overlooked was oxidation. When disintegrated it became oxidised, and naturally got much less valuable. Mr. Crompton said the locomotive boiler was not efficient on account of the level of the fire bars. Well, it was evident that it could not be efficient. In point of fact, they had taken the locomotive boiler lock, stock, and barrel, and adopted it exactly and absolutely, like the Chinese. In 1872 some beautiful results were obtained by Clayton and Shuttleworth, at Cardiff, which had never been equalled, either before or since. What they did was to carry the foundation ring up semi-circularly instead of having it along the front of the box ; they brought it up in horse-shoe fashion, and got the fire-bars lower down. If they found a boiler evaporating 3lb. per square foot per hour, and doing an evaporation of 10 or 11½lb., and if they multiplied those figures into one another, they would get a curve giving them more light. It was possible to pay too much for a sovereign, and if they had, as Prof. Kennedy had said, an economy of 11½lb. when they were burning only 6lb. of coal per square foot of grate, why that was simply doing nothing. Mr. Crompton told them one boiler was doing 50 per cent. more than its work without getting into trouble ; but all he (Mr. Halpin) said was, "Thank you for nothing." That particular boiler was doing under 3lb., and 50 per cent. more made it almost 4½lb. With regard to the Lancashire boiler, some trials were made by the South Lancashire Company coal owners, some thirty years ago, with boilers 7 × 30, using Northern coal. The tests were very accurately made, and these were the results as the average of 60 trials : The boilers evaporated 7·1lb. per hour per square foot of heating surface. They were using coal with 11,670 units, and doing that from and at 212deg., which, reduced into thermal efficiency, meant 827. So they got 7·1 × 827, and that gave them the figure of merit 5,871. The Babcock boiler he had taken was evaporating on that trial 2·893lb. per square foot per hour. The efficiency of the coal as given by Mr. Crompton was 766. Multiplying those two numbers together they got 2,245 ; that was to say, they got 58 as the figure of merit for one boiler, and 22 for another. He must go one step further. Mr. Rosenthal had given him the price of several of the Babcock boilers, and he had taken out what it came to in heating surface. The Babcock boiler cost on the average 6·21s. per square foot of heating surface. He had also obtained the prices of five standard Lancashire boilers, and their price was very much higher—8·74s. per square foot of heating surface. So that now, if they divided the results of the factors of efficiency they had got, by the prices forming the capital cost, they got something like a final figure for the efficiency. If they divided this 58 by 8·74 they got a figure of merit of 6·6, whilst with the other boiler they got an efficiency of 3·6. And that was quite apart from all questions of the Lancashire boilers being able to use dirty water and smoky coal, which he hardly thought the other people would claim for their boiler, good as it otherwise was.

*Mr. ROSENTHAL said that during the last three or four years a good many electrical engineers had thought that the best thing to do was to put in Lancashire boilers in central stations, particularly in places where coal was cheap, and the question of space was of no consequence. He had not been able to obtain any very complete data as to the results obtained in those places, but the average experience in the north of England of the

Digitized by Google

working of Lancashire boilers in ordinary factories certainly went to show that the result was not more than an evaporation, as a rule, of 6 to 7lb. of water per pound of coal. There were trials on record, as Prof. Unwin had mentioned, of magnificent results obtained with Lancashire boilers. But those results were no criterion whatever for the design of a central station, because, excepting in a very few instances, it would not be possible to put as much boiler surface down in Lancashire boilers as would be required to work at such a rate as would ensure the efficiency that was held up. The question of safety, of course, had always to be considered, and the question of upkeep likewise, and it was a very questionable thing whether a Lancashire boiler was under any condition a good boiler for high working pressure. At the Popp compressed air station in Paris an indicated horse-power hour was produced with 500 grammes of coal containing about 14,000 B.T.U., which was equivalent to 1-2/10 per lb. of English coal, and only a day or two ago he received particulars of a plant of Babcock boilers in Calcutta working in connection with a triple expansion condensing engine of 2,000 H.P., where the results amounted to the production of 1 I.H.P. hour with 1¾lb. of Indian coal, about equivalent to 1-2/10lb. of Welsh coal, so that it seemed they were not very far off the figures that Mr. Crompton mentioned as possible. It was said sometimes that a Lancashire boiler was better than a water tube or an ordinary tubular boiler in respect to the prevention of smoke. If they worked a Lancashire boiler very lightly indeed with a class of bituminous coal that easily coked, they could undoubtedly fire it to produce very little smoke. On the whole they might take it that a Babcock boiler or ordinary tubular boiler, to burn bituminous coal smokelessly, required mechanical firing, and so did a Lancashire boiler. Mr. Halpin had given them a number of figures as to the evaporation per square foot of a Babcock boiler compared with a Lancashire boiler. He submitted that it did not matter to the electrical engineer what the surface of the boiler was so long as he obtained a certain quantity of steam for a certain quantity of coal, and the total power he required cost him the same amount of money. With regard to burning oil, he certainly thought that oil fuel would be used to some extent for dealing with some loads in an electric light station. There was no difficulty whatever in applying oil to an ordinary boiler burning coal, and it could be used at a moment's notice, but no such fancy results were to be obtained as Mr. Henwood had claimed, and so far as the wonderful type of boiler he had sketched was concerned, that was simply a Yarrow boiler with the tubes connected in such a way that they could not possibly be cleaned, and that would not do for an electric light station. The question of dryness of steam was one often discussed. The last case in which he had heard of wet steam was at Deptford, and upon investigation it was found that the steam as it came from the boilers contained only three-tenths of 1 per cent. of moisture, and the wetness was produced in the steam pipes, which was the most prolific source of the trouble of wetness of steam in the engine.

*Mr. R. E. B. CROMPTON said he perfectly agreed with Prof. Unwin as to the splendid results got from the Lancashire boilers; but he (Prof. Unwin) left out the very thing which Mr. Halpin supplied, *i.e.*, the rate of firing. It was the high rate of firing necessary in an electric light station which made the Lancashire boiler comparatively inefficient. It was of no use trying to explain results away, and it was the fact that there was hardly a Lancashire boiler station which was doing well; there were exceptions, but they were due to the great skill and unwearying attention of the engineers in charge. There was not the same difficulty with the multitubular boilers of the locomotive, semi-marine or Babcock type. They had all done good service in their stations. Major-Gen. Webber's remarks were nearly every one of them based on misapprehensions. Mr. Robinson and others said his ideal figures were pitched too high. He might possibly be wrong in that respect, but he wished them to be high and difficult of attainment. He thought with Prof. Kennedy that 4¼lb. was reached every day now in some of the best stations per unit sold to the customers. If that was reached already, and as they knew, there were very considerable and preventible losses still remaining, it was to be assumed that they would get 3½lb., but beyond that he admitted it would be a very stiff pull; but why should he not give them 2½lb.? It was absurd for them to have a standard, we should soon be like the old Matthiessen's standard of copper, having a 104 per cent. efficiency. He was interested to hear Mr. M'Laren's remarks. Everyone knew that Mr. M'Laren was the builder of record engines, engines which had done very high duty, and he was especially pleased to hear that he was the builder of the engines at Oxford, where the results were so good. He wished to say that he never intended to throw any doubt on Mr. M'Lean's figures. The results were wonderful, but they were obtained in the proper way, that was, by measuring and watching everything and analysing the losses. That was the sermon he had endeavoured to preach to this Institution almost constantly for the past six years. With regard to the remarks made that evening, he had already stated, in answer to Mr. de Segundo, that it was not so impossible to get to his ideal; he admitted it was difficult, but not impossible. He thought Mr. de Segundo forgot that Sulzer and other Continental makers had been getting 13lb. with condensing engines pretty regularly for some time past, and he fully expected to hear that they had done it in electric light stations. It might interest Mr. de Segundo to know that even in high speed engines, Messrs. Willans and Robinson were giving trade guarantees of 13½lb. per I.H.P. hour. He was very glad to welcome the remarks of Mr. Shoolbred and another gentleman who spoke on the subject of the advantage of using accumulator storage. That was a theme upon which he had harped, and regarding which many strong things had been said of him; but it was well-known that, especially in the smaller class of stations, the saving in the wages account was very considerable from the use of accumulators, and the saving of coal by being able to run the engine at a better load factor was also considerable. He was glad to say they had brought this home to the American mind, and in New York some of the large stations were being worked by accumulators, and they were getting an infinitely better supply of electric current at a lower cost. The information which Prof. Unwin had given was very valuable, especially that with regard to superheating steam. He had listened with great interest, and had learnt a great deal. He had known for some time past that this was a development from which they would get greater economy. He had already pointed out that the flue type of boiler required to be fired regularly, in order to get the high results mentioned. He could corroborate what had been said regarding the advantages of the "Economic" boiler from personal experience. One of the most important points that had been raised, to his mind, was that mentioned by Prof. Kennedy, who said he had noticed that when they got to 3,000 or 4,000 H.P. they had reduced the generating cost almost as much as they could possibly do. That was a thing he had wished to say himself for years past in the old controversy about putting large stations outside a town instead of having smaller stations inside a town. It apparently never struck those who had been urging this great change that there was no advantage gained in making the size of a station above a certain figure, a figure which Prof. Kennedy had put at 3,000 or 4,000 H.P., and with which he perfectly agreed. Several speakers had thrown doubt upon the possibility of the use of liquid fuel being carried out successfully. He thought the peculiar conditions of electric lighting, with that peculiar peak on the curve, in every way pointed to the use of liquid fuel, and also the very rapid rate of evaporisation in the boiler which could be given with liquid fuel. His own Company, and one or two others, were experimenting in this direction, and, no doubt, when next a Paper on this subject was read before this Institution, they would have successful results to record. It appeared to him that if one could call on a second boiler at 20 minutes' notice, and heat it up, as he had seen done with the use of liquid fuel, they were having an ideal state of things as regards boiler plant in an electric light station; and he might say that the introduction of liquid fuel would, in his mind, increase the possible output of many existing London stations, some 40 or 50 per cent., for in nearly all those stations the future limit of expansion was bounded by their boiler power, and not so much by their steam-power. The interest taken in the Paper repaid him in every way for the trouble he had had in writing it, and he could only repeat that his object was to elicit from those who knew the subject best, that was to say, those who worked in those stations, what their real opinion was on the progress of their art, and he thought they had every reason to be satisfied with the progress which had been reported to them, and at getting such figures as Prof. Kennedy had given them of 4¼lb. of coal per unit delivered to customers.

DESTRUCTIVE EFFECT OF ELECTRICAL CURRENTS ON SUBTERRANEAN METAL PIPES.

The following is an abstract of the discussion which took place at New York and Chicago on the Paper on the above subject read by Mr. Isaiah H. Farnham before the American Institute of Electrical Engineers. This Paper appeared in *The Electrician* of May 4th. The full report of the discussion will be found in Vol. XI., No 5, of the *Transactions* of the American Institute.

DISCUSSION AT NEW YORK.

Prof. Geo. W. PLYMPTON: My first experience with electrolysis dates from about a little more than a year ago. In framing the franchise for the trolley roads there was fortunately a clause inserted which placed responsibility upon the trolley companies for any mishaps to any underground pipes, wires, cables or the like. That was placed there, not because electrolysis was thought of at the time, I think, but because it was supposed that in the process of digging up streets they might interfere with gas and water pipes. I am sorry to believe that we have not got the full measure of the damage that has been done. So much as has been exhibited was such as has made itself known through the entire failure of pipes and cables. It is reasonable to suppose that ten times as many examples could be found which would be nearly as bad as those exhibited, because there has been no digging down in the ground in search of such cases of corrosion. Water pipes, gas pipes, and lead coverings of cable have all suffered. Telephone companies were the first to find it because of slight perforations of the insulation. Leakage of water pipes have made themselves known in one or two cases where they were near enough to the surface. In one of the cases exhibited, one pipe had been destroyed in three or four months. It was an iron pipe very near the rail. It was replaced by a larger pipe, and that was perforated in 30 days. So that the rapidity of the action warned us there that it was time to look about quite actively. We have held numerous conferences with the engineers and they have promised to take all proper means for taking care of their own current. One thing I feel a little concerned about, and I take time only to mention it and that is this seventh conclusion:—"A large conductor extending from the grounded side of the dynamo, entirely through the danger territory and connected at every few hundred feet to such pipes as are in danger will usually ensure their protection." True, so long as that connection can be kept up. Will it not be necessary to make such a connection in such place that we can examine it every once in a while? Will it do to make a connection and cover it up? What shall it be—copper wire? Can we solder a copper wire to an iron pipe? Can we make a connection that will remain good and without increasing its resistance? Local action will set up a corrosion, and as to soldering, in the ordinary sense of the term, it seems to me impracticable. So that we have some fears that whatever precautions they take of that kind, may prove insufficient after

Digitized by Google

a little while or else that they will need constant attention and that we shall need a large corps of inspectors to prevent serious injury. One, that of making the rails continuous, has been, I believe, tried in Boston. It is about to be tried in Thirty-ninth-street, Brooklyn. The apparatus arrived the other day for welding the rails. The engineer of the Company assured me that they would make their rails continuous within the limits of the city. The question with us, of course, is in the experimental stage. We shall accumulate more within a year, but in that time I fear we shall find a good deal more damage done, for the reason that it is only where the corrosion has been so bad that the pipe or the cable has failed, that our attention has been called to it.

Mr. A. E. KENNELLY: I wish to take the stand that it is not, as stated in the sixth generalisation, necessarily good policy to connect the positive pole of the dynamo to the trolley lines. When you arrange the current, as is suggested as advisable in the sixth conclusion of this Paper, all the distant district is free from danger and all the oxidising and corroding effect is close to you. The danger area is reduced, but the danger is greater, because the activity is consequently augmented in that district. But if, as Mr. Farnham says, we prevent that, as was done so skilfully in this case, by throwing out a ground feeder, which prevents the current from emerging out of the pipes into the surrounding soil near the power house, why then, coupling together the sixth and the seventh conclusions, all is well; you have stopped the corrosive action. But unless you do couple together the sixth and seventh suggestions, you are likely to cause more danger by having the positive pole to line, than if you have the negative pole to line. Furthermore, I would like to point out that the difference of potential as measured by a voltmeter between a cable sheathing and the ground in its vicinity, is not necessarily a criterion of the degree of corrosive activity taking place at that point. For suppose you had a perfectly insulated cable and sheath, but at some distant point, say, half a mile off, the sheathing of lead was exposed to the ground, and that there destructive action was being produced, there might be at that point, half a mile away, a difference of potential between sheath and the ground of three volts; but at the point where you stand the potential difference might happen to be five volts. Now, the five volts could not be so active in producing corrosion as the distant three volts, in fact it could not be active at all, owing to the perfect insulation of the entire cable in the vicinity. Again, while all admit that iron pipes are corroded electrolytically, we all know a given weight of lead is much more readily consumed by electrolysis than a given weight of iron. Roughly, an ampere in a year will dissolve seventy-five pounds of lead by electrolysis. It will dissolve, roughly, only about twenty pounds of iron. The destructive effect of electrolysis, while it is serious, is often exaggerated by not taking into account the actual amount of decomposition that can take place, electrolytically, under the most favourable circumstances. If you have a mile of eight-inch water main, which is half an inch thick, that is, its exterior diameter is nine inches and its interior diameter is eight inches; and a thousand amperes are kept steadily flowing day and night, with uniform density, out of that surface into the surrounding soil, it will take about six years for that current to reduce, by electrolysis, the thickness of the iron to one-half. Of course, it would be unfair to make a positive statement of that kind, because we assumed uniform corrosion, whereas corrosion does not take place uniformly. One of the most interesting observations that ever fell to my lot, in connection with the high resistivity of the ground, is, perhaps worth mentioning. It was occasioned by trouble in an Edison tube, and the fault, a ground, was situated about three-quarters of a mile from the station. We were trying to locate the ground by means of a compass needle moved over the surface of the soil and over the buried conductor, while strong direct currents of about two seconds duration were applied with ground return circuit, every three or four seconds in the power-house. We took the magnetic needle along the surface of the trench and tried to find a point where the needle ceased to respond to the intermittent currents. We came to a spot where the line of Edison tubes departed from the road and entered a field. Round the field there was an iron wire fence with iron uprights, which fence ran for several hundred feet parallel to the road. We knew that the ground existed in the iron Edison tube somewhere in this vicinity. I happened, quite by accident, to stand near the fence, looking in at the field and wondering where the trouble might be, and as I rested my hand on the fence I fancied I felt a shock. I thought this a mere delusion, and paid no attention to it. But presently some one else came up, and without any suggestion on my part rested his hand also on the fence, and declared that he felt a shock, and finding my own imagined sensation corroborated independently, we investigated it and found the reason to be this: within 20ft. of the fence was the "ground" we were seeking in the Edison iron tube. The intermittent current escaping from the conductor into the iron tube 30in. below the surface of the soil, was able to raise the potential of the surface of the road in the vicinity where we stood, to such a degree that we were able to deliver through our hands enough current to the iron fence wire to make a shock perceptible, and, on taking measurements later on with a galvanometer we found the resistivity of the soil, which was damp, but not wet, to be something like 60 ohms.

Mr. FARNHAM: I would like to say in reply to the able remarks just given to us, that there would be no advantage in doing some of the work suggested unless we did other parts of it also. Conclusion No. 6 was intended to go with No. 7. But if that had not been the intention, I can hardly agree with the speaker that it would be more serious to have the corrosion take place in a limited territory, even though it were more rapid, than in a large territory. Would it be more convenient to dig up all the paved streets of a large city once in 10 years, or to dig up a radius of a thousand or of two feet once in a year? It is an open question which hydraulic and gas engineers must pass upon. Whatever we do to remove danger we must watch the electrical conditions constantly, or we shall find ourselves again in trouble. In illustrating this fact, let me say that since the system just described has been applied in Boston, the West End Company has run out in one direction several large return wires in addition to those previously in use in that locality, and thus practically moved the power station, that is, it changed the zero line from its former location to a point very distinct making it necessary to rearrange and extend the cable return wire system.

Prof. HOUSTON: I think one of the most interesting points that has been brought forward in this Paper, and one which has surprised me very much is the exceedingly small potential difference which the Paper states has been necessary to effect electrolysis. I should, however, look very carefully at the source used, and the method by which the experimenter assured himself that he did actually limit the potential difference to the small fraction stated.

Dr. LEONARD WALDO: The coal miners have had much trouble in keeping their valves from disappearing and their pipes from being eaten up, and inasmuch as we have been interested in the metallurgy of that sort of thing lately, we have looked into the question. In several instances we have had valves, parts of pumps, and similar articles sent to us from the depths of the mine, and several gallons of the water which was supposed to do the mischief sent along with them. We boiled the water holding specimens of the metal of which the valves were made, and exposed the specimens for weeks at a time, with no chemical action at all on the metal similar to that used in the valves or in the pipes. When you insert an iron pipe and connect the two specimens through a voltmeter, you will get a very rapid disintegration of one pipe or the other, and you get an indication of anywhere from four to six-tenths of a volt. It is my observation that very efficient deterioration of these underground materials of different potential takes place with differences under half a volt. In all these questions of rapid deterioration of pipe, I think, the most important consideration will have to be given to the actual corrosion which occurs because of the molecular, chemical, and electrical action which take place between the metal and its own impurities.

Dr. CHARLES E. EMERY: In that connection I will say that it is found in practice that a steam pipe covered with a non-conductor, and maintained at a temperature of 250°F. to 300°F. will not corrode underground, whereas a hot-water return pipe similarly covered and kept at about 212deg. corrodes very rapidly. The corrosion is external, and appears to be ordinary rust. A study of the phenomena indicates that there is a critical temperature where the gases in the soil act more intensely than at other temperatures. Apparently ordinary carbonic acid gas has the most important influence. It appears, therefore, that the temperature should be considered in connection with the other influences on corrosion which have been mentioned.

Communicated by Prof. ELIHU THOMSON: May we not be justified in expecting that in many cases the natural corrosion may be even arrested by the negative polarisation of the pipes with respect to earth? Could every line of pipe be relied upon as a complete conductor without bad joints, the problem of protection would be much simplified, but the current in crossing a bad joint in a line of pipe will undoubtedly be partly shunted through the earth around the resisting joint, and cause corrosion to a greater or less extent. Again, if in a line of pipe every joint was of poor conductivity, there would be very little chance of corrosion by electrolysis, as the pipe line would not offer any good path for current. Earnest endeavours will be made in the present year to prove the practicability of continuous rails electrically welded in place. In cities this would give a network containing a vast amount of metal in the rails, acting as a conductor for the return current. Such a track system, or even a track system well bonded, would, if worked with a zone system, in which successive zones of trolley conductor are made positive and negative respectively, remove all possibility of trouble, but might increase the risk in the accidental crossing of wires on the trolley conductors. Another system of working which would remove most of the difficulty in our cities, would be the employment of potential reducing motor generators at various points over the area, the high potential side being fed direct from the power station by metallic circuit, and with either alternating or continuous currents, as found most expedient; while the low potential side, 500 volts or less, would go to trolley wire and track respectively. In this case the return current would never have to travel very far, and the drop on the whole system would be much lessened. Copper would be saved, and the congested districts could be readily supplied with a lower potential than the high speed outlying districts. If alternating currents were used from the power station to the motor generators, the generators in the station could be made of very large capacity, say 5,000 H.P. in a large city, and the motor generators could range from 200 to 500 according to the density of traffic, &c. I mention these facts to show that avoidance of all electrolytic corrosion is within the capabilities of electrical engineering, while still retaining the continuous-current motors on the cars, and the single overhead trolley wire. It is even possible that considerable economy of transmission might be secured over the direct-supply systems as now used.

Communicated by HERMANN LEMP, JUN.: Having been intimately connected with the experiments carried out in Cambridge during last summer and winter, I think a few remarks in reference thereto will be interesting at the present time. The tracks experimented upon were all, before any welding was done, condemned by the West End Company. The original method consisted in welding two U-shaped yokes on either side of the joint through the web of rail. Of the welds made on Main-street, Cambridge, about 10 per cent. have broken through the winter. It was soon discovered that the method of welding first used was not quite satisfactory, as it produced a local strain in the rail by heating only the web part of the rail to a welding heat. Experiments were made at once with a view of welding the rails *right at the joint*, and extending over the whole surface of the rail, including rail and foot. The season being already far advanced when these experiments were concluded, only a part of the track in Cambridge could be provided with new joints. Every one of these

Digitized by Google

welds stood through the winter without a break, with the exception of one which broke the day it was made, and showed poor workmanship. From all the experiments made up to date we can draw the following conclusions:—(1st) A continuous rail can be used for electric street rail-car practice with absolute safety if an expansion joint is inserted every 600ft. 2nd) A continuous rail can *probably* be used without any expansion joint by using the latest method of welding. (3rd) The electric conductivity of any joint is as great as the rail itself. (4th) All joints being of the same material and continuous even when elastic, will not change by vibration, heating or electrolysis. (5th) By frequently cross-connecting the rails—making up a track of electrically welded joints, any trouble from interruption in the track can be obviated. (6th) The resistance of the feeders from track to power-house is immaterial aside from *economy*, provided the ground in power-house is taken off.

DISCUSSION AT CHICAGO.

Mr. B. J. ARNOLD: The subject of electrolytic action of the railway current on underground pipes and conductors is now being agitated in almost all cities where railways have been running long enough for the destructive effect of the current to make itself known, and it will not be long before we shall hear from it in our own city, if the many ordinances now being considered by the Council are passed without some stipulations regarding the construction and carrying capacity of the rail return circuit of the roads which the companies propose to build under these franchises. I am of the opinion that if the rails are supplemented by a system of feeders, so that the resistance of it is not greater than that of the outgoing circuit, and the rails joined with a bond equal in conductivity to the rail itself, which is most effectually accomplished by welding the rails together electrically, that the entire difficulty caused by electrolysis will disappear. The suggestion of Prof. Thomson of the application of motor transformers for the purpose of relieving unequal potentials seem to be impracticable to construct, as well as difficult to look after, as it would necessitate numerous electric motors running in various parts of the city, the location of which would have to be changed from time to time to correspond to the fluctuating danger line, and would result in constant expense for maintenance as well as a large additional equipment. Mr. A. C. Balch, of Portland, Oregon, in a communication to one of the railway papers recently, described the method of using the three-wire system on the electric railway in that city. The trolley is divided into sections of about 1,000ft. in length, the positive wire of one dynamo being connected to one section, and the negative of the other dynamo to the adjoining section, while the neutral wire is connected to the rails. It will be noticed that with this arrangement there is a difference of 1,000 volts between the adjoining sections of the trolley wire, but as they are thoroughly insulated and the motor cars pass from one section to the other quickly, there seems to be no difficulty caused by the sudden reversal of the current through the motors when passing from one section to another. So long as the cars are properly distributed on the line, I see no difficulty in the operation of an electric railway with the three-wire system, but if the cars were to become "bunched," as sometimes happens in large cities, the feeder wire supplying that particular section would be overworked, although I do not regard this difficulty as serious. With this arrangement the electrolytic action on pipes is almost, if not entirely, avoided, as there is practically no current flowing from the trolley to the earth when the road is working under normal conditions. I believe there is also a three-wire electric road in operation in Bangor, Maine, and so far as I am able to learn it is working with entire satisfaction.

Mr. A. T. WELLES (of the Western Electric Company): I wish to say that Mr. Farnham has unintentionally misquoted me, as was also the case in the interview in a Cincinnati Paper which brought about my correspondence with him. The statement would lead you to suppose that some electrolytical trouble had developed in cables laid by my Company in Cincinnati, but this is not the case as far as I know. I simply wish to make one other statement. Since Mr. Farnham collected the data for his Paper, we have run across another very peculiar case of electrolysis in Cleveland. A cable which my Company laid there in January last for the Postal Telegraph Company was reported as having given out entirely about two weeks ago. The cable ran from their office down about 1,500ft. and then through a tunnel about 80ft. deep under the river. Through this tunnel a large water main also runs. A splicer located the trouble in the manhole at the mouth of the tunnel, where he found the cable pipe entirely eaten through. Mr. L. L. Summers, of the Postal Company, made voltmeter and ammeter tests at this place and found 18 or 19 volts on the cable, and also on the water main in the tunnel and 45 amperes current. The cable pipe was eaten through in ten weeks. What is going to become of that water main and what is going to become of that tunnel?

Messrs. PAUL BIEFELD and FRED. SILBER communicated the results of an investigation carried on in the laboratories of the University of Wisconsin, and along the line of the electric railway of Madison, Wisconsin, under the direction of Prof. Dugald C. Jackson. The line has been in operation for about a year and a half, having nine car in service, but no troubles due to corrosion have shown themselves thus far. Measurements of potential between water pipes and rails, near power station, show a difference of 4½ to 5½ volts, water pipe being positive to rail, and 2½ to 3½ volts between water pipe and the earth near the rail, water pipe being positive to earth. The potential reversed at a distance of from 1,600ft. to 1,800ft. from the station, the range being zero to four volts outside of this neutral zone, the water pipes being negative to rails and earth. Experiments are at present in progress to determine the actual current flowing between pipe and rail. This is done by means of a modified form of a copper voltameter devised for this purpose. A water-tight box containing a solution of copper sulphate is buried in the ground. This box has for two of its opposite sides, facing the pipe and rail respectively, double copper plates, of which the inside ones are weighed. The gain of cathode will then give in the usual way an integral measure of the current. A series of experiments to determine the minimum potential at which corrosion may go on between iron plates showed that a mere *directive force* was needed; the potential having been reduced to 0·001 of a volt, electrolytic action still went on. In each case the action was manifested by the formation of a ferrous salt at the anode, and the hydroxide of the alkaline metal at the cathode. This phenomenon shows at once the cause of the corrosion. The main object of our investigation has, indeed, been to determine exactly what goes on in an electrolytic cell under parallel conditions to those found in practice. Whenever iron electrodes were used with soil or sand containing small quantities of soluble salts in solution, a layer of ferrous hydroxide was invariably formed at some point between the two plates. The earth used was found to contain small quantities of chlorides and sulphates of the alkaline metals, and showed no trace of soluble iron salts or alkaline action before electrolysis. After the current was put on ferrous salt began to be formed at the anode spreading toward the cathode; the hydroxide of the alkaline metal was formed at the cathode spreading toward the anode; where the two met a layer of ferrous hydroxide was precipitated, recognised at once by its dirty green colour. In all these cells a peculiar heating effect was noticed, reaching a maximum in the ferrous hydroxide layer, and diminishing in general toward the electrodes. Measurements of potential taken within the cell at different points between the plates showed the greatest difference of potential at the zone of maximum temperature, and a diminishing difference in the same way as the thermometer had shown a fall in temperature. It must be stated here that the readings of potential were taken when no appreciable heating effect was noticed, only a very small and constant current flowing at that time. These observations show that the unequal heating was caused by unequal resistances in different parts of the cell due to the formation of the hydroxide layer, together with the unequal concentration of the iron salt and the alkaline hydroxide, which diffuse toward the point where the precipitate of iron hydroxide is formed. A similar variation of temperature, only much less marked, showed itself in a cell containing pure sand (practically free from soluble salts) and distilled water. The theory has been put forth that the corrosion is due to the electrolysis of water, the nascent oxygen attacking the iron at the positive pole. In the first place, there is no electrolysis of water, oxygen and hydrogen being in each case set free at their proper poles by virtue of secondary reactions. The fact, however, that nascent oxygen even then does not attack the anode when the iron electrodes are used is clearly pointed out by an experiment, wherein six such cells were run in series at 100 volts terminal pressure, the current varying from 0·2 to 0·4 amperes during the experiment. The electrolytes consisted of pure glass sand saturated with a one-third of 1 per cent. solution of chemically pure nitrate of ammonia, chloride of ammonia, nitrate of potash, chloride of potash, nitrate of soda, and chloride of soda respectively. The real facts and explanation are given in the following conclusions:—In an electrolytic cell with iron electrodes, having any salt or salts of the alkaline metals or earths in solution in the electrolyte, the salts are electrolysed: their acid radicals attacking the anode, forming an iron salt. The metal set free at the cathode forms with water the hydroxide and liberates hydrogen. The ferrous salt diffuses toward the cathode, the alkaline hydroxide toward the anode, and at the point of meeting the ferrous hydroxide is precipitated and the original salt reformed. As the amount of electrolysis varies directly with the strength of current, a comparatively high current will liberate an excess of the acid radical; the critical point depending on the affinity of the radical for the iron, the surface exposed being the same. This excess forms in the presence of water an acid, and liberates oxygen. Neither the acid nor the oxygen have any effect on the iron, the anode being already engaged in the formation of the iron salt with the acid radical. Hence the oxygen escapes, and the acid diffuses through the electrolyte. The last experiment, together with the fact that the ferrous hydroxide layer invariably forms at some distance away from the anode, points very strongly to the conclusion that the corrosion is *solely due to the attack of the acid radical of the salt originally in the electrolyte*. As chlorides, sulphates and nitrates of the alkaline metals and earths are almost invariably found in street solids, and as a mere directive force in the way of an electric pressure is required to set up an electrolysis of these salts, it can be plainly seen that the iron pipes may be corroded wherever the potential at the latter is positive to the rail. The amount of corrosion in a given time only depends upon the amount of the current and the nature of the salts in the soil.

Mr. C. G. ARMSTRONG: Some years ago I was requested to inspect an electric railroad in Indiana, where I had some experience with the erratic action of electricity under ground, and where I made some measurements of differences in potential between adjacent conductors. Unlike Mr. Farnham I did not use a voltmeter, but used a mule, that is to say, the owners had noticed a variation in the operation and speed of their motors at a certain point. I watched a mule team driven over this place and found that at a certain point one of the mules became very much agitated, to the extent of planting his hind feet on the dashboard of the waggon many times in rapid succession. I had no means of calibrating the mule, but would judge that the potential difference must have been considerable at this point, and upon inspection I found that the rail bonds were broken, and a very disagreeable shock could be felt by touching the ends of the rails at this point. The construction of this plant had been very unscientific, and extreme differences of potential could be found in different parts of the town, but being only a country village with few pipes and fewer scientists, the matter of destruction to anything except the railroad property itself by reason of this faulty work was not thought of. I cannot feel that electrolysis is guilty of all things charged to it. I do not believe that every defective water pipe and gas main was destroyed by electricity. I have seen miles of water and gas pipe that was in much worse condition than that shown to-night, where the nearest electric wire was 20 miles

Digitized by Google

away. I believe the gas companies are responsible for two-thirds of the trouble found in pipes to-day. Where we dig up the streets we find the earth permeated with ammonia and other destructive products of the gas retort, which within themselves are sufficient to attack and decompose any metal they come in contract with; in fact, one of the pipes shown was a gas pipe, and there was a serious decomposition of the metal on each side of the union. The author of the Paper attributes this to the resistance of the union; why might it not have been the leakage of the gas? I have found gas pipes that could not possibly be acted upon by electricity that were decomposed in exactly the same manner, from the gradual leakage of the gas. Undoubtedly we are guilty to a certain extent for the destruction of underground pipes, and the cause I believe can be removed. The use of the three-wire system as mention by Mr. Arnold is undoubtedly one solution, but offers complications. The use of the return wire as suggested in the paper is another remedy, but one which I am afraid will greatly interfere with the "returns" at the meeting of the stockholders. As mentioned in the Paper, every additional pipe protected reduces your protection to all others, and to obtain absolute protection it would be necessary to literally fill the ground with copper wire and have the different resistances nicely and mathematically balanced, and even then, with a large number of cars at the extreme end of the line, the resistance might be thrown out of balance, and electrolytic action result therefrom. I think this problem should be viewed just as we do that of wiring a building, viz., to avoid grounded circuits insulate both poles, and thereby dispense with electrolysis, danger from fire, and at once solve the difficult problem of lighting arresters for grounded circuits. There seems to be no practical difficulty in the use of the two trolleys. I really do not see, after all, why it is not the best way out of the present difficulty. It certainly would not cost as much to run a double trolley system as it would to run a complicated system of underground returns connecting to all water, gas, and other pipes, and what not that we meet in the street.

Mr. A. V. ABBOTT, on behalf of the author, said: The double trolley system certainly does afford a perfect solution, but only at the expense of a greater investment of capital. The objections to the double trolley system, other than those of increased capitalisation, are entirely mechanical ones and in ordinary lines can be overcome. The double trolley about three years ago still survived, and it is probably chiefly due to the Thomson-Houston Company that it does not still exist. In all railways which are reasonably straight, and do not encounter a great number of intersecting lines, the introduction of the double trolley is not a serious obstacle. Personally, I have always been in favour of all electrical companies operating entirely upon metallic circuits which should be peculiarly and appropriately their own. A conduit electric road is at the present time perfectly feasible, and its successful construction and operation is merely a question of the amount of capital that the promoters are willing to invest. Ordinarily speaking, an electric road can be built and equipped in running order at an expense of from thirty to forty thousand dollars per mile including all items, excepting that of real estate, franchises and buildings. The cable road is typical of the conduit system, and is always expected to cost from 125,000 to 150,000 dollars a mile. The widespread and rapid introduetion of electric roads has chiefly resulted from the fact that they require so much smaller capitalisation in the outset, and that they, therefore, may be introduced in districts that are not thickly settled, in which the traffic could never be made to pay the interest and depreciation on the more expensive cable plant. In building some 300 miles of electric road I have universally found that the grounded return circuit absorbed more energy from the station than any other part of the line, the car motor only excepted.

THE HATCHET PLANIMETER.*

Planimeters, or area-measurers, are apt to be regarded at first thought as necessarily difficult to understand, and mathematically complicated. When examined more closely, the mystery is resolved into very elementary principles, beautifully simple, and very interesting to engineers, who are always more attracted by geometry than by mathematical analysis. The most ingenious instruments by Amsler are well known to most of our readers, and they will, therefore, not be further referred to in this article; they maintain their superiority over all other instruments of this class. The hatchet planimeter, the invention of H. Corn Kundsen, of Copenhagen, is in construction the simplest of all planimeters. It was exhibited at the Physical Society on March 23rd, by Prof. Henrici, in connection with his Paper on "Integrating Instruments," and it was then remarked, that a mathematical demonstration of its action was still a desideratum. The following exposition of the geometry of the hatchet planimeter will therefore, we hope, be interesting to many of our readers.

The hatchet planimeter is merely a trammel of fixed length, with, at one end, a tracing pointer, and at the other end a tangent keel pointer or knife-edge called the hatchet; the edge is as at F in Fig. 1, curved, so that, although a keel edge, it may still be regarded as a tangent point. Fig. 1 shows the planimeter inverted. Here the length from keel point to tracer point is $1\frac{1}{4}$in., too short for general use, but this length has been chosen now to more clearly exhibit the geometry of its action. The keel edge F is, of course, in the same plane as A.

The boundary of the figure, whose area is to be ascertained, is traced continuously, in one direction, with the tracer pointer A, while the hatchet or keel end of the instrument, describes a path from which the area of the figure can be directly measured.

* Abstract from *Engineering*.

The boundary of any figure can be resolved, elementarily, into ray and arc alternately, *i.e.*, into elements in the direction of the planimeter arm and elements normal to the arm. While tracing a ray element the arm does not alter its direction, and while tracing an arc element the hatchet tangent point does not alter its position. When these are indefinitely minute, the coincidence of outline will be perfect.

In Fig. 2, A B C D is an arc-and-ray figure, B C and D A are arcs, and B A and C D are rays. Draw the straight line G A

Fig. 2.

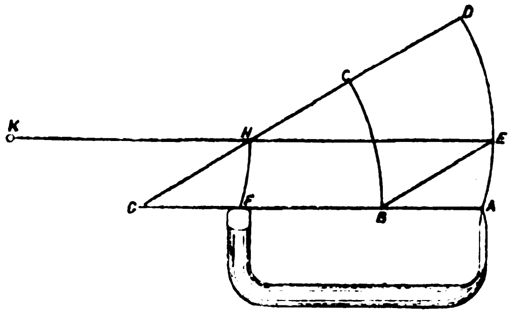

Fig. 1.

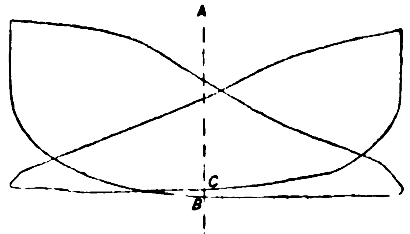
through B, and call this the axis. The planimeter has its initial position on this line at F A. Of course the planimeter is applied in the vertical position.

* While the pointer traces .... A B C D A
the hatchet describes........................ F G G H H

To complete F G H draw the straight line K E through H parallel to the axis F A, and describe the arc H F from K with radius K H = F A, the length of the planimeter. Draw B E parallel to C D. The figure F G H, which we may call the keel field, is evidently equal to A B E, and the figure B C D E = the parallelogram B G H E, because the one figure could be changed into the other by shearing parallel to E B. Introduce now L = length of planimeter, and Y = perpendicular distance of the final keel position H from the axis G A. Since H E or G B = L, the area of the parallelogram H B is equal to L Y, and the area of the whole figure C A is L Y + the area of the keel field F G H = A B E.

Fig. 3.



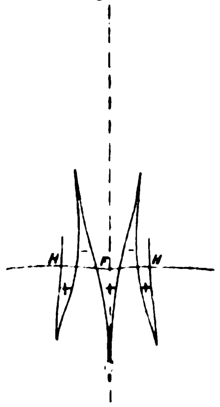


Fig. 4.

In Fig. 2 we have only one arc-and-ray element, but just as the outline of any figure may be regarded as made up of indefinitely minute arc and ray elements, so also any area may be regarded as made up of arc-and-ray elemental bands.

Some engineers who have used the instrument say it is very suitable and quite accurate for indicator diagrams. Fig. 3 is a sketched pair of diagrams, and Fig. 4 is the keel path in the appro-

[* While the pointer traces A B, the hatchet describes F G.
" " B C " " stands at G.
" " C D " " describes G H.
" " D A " " stands at H.—ED. *E.*]

Digitized by Google

priate position; G A is the axis, it extends across Figs. 3 and 4. The planimeter is in this instance 8in. in length, or twice the length of the diagrams. The hatchet is placed on the axis at G, and the diagrams are traced in opposite directions, preferably in the same directions as they are drawn by the indicator. The keel paths are then easily manageable, and a little experience teaches at what point in B A the tracing should terminate. Really, the tracing ought to commence at the same point at which it ends, but, as the initial movement down A B would merely describe a portion of the axis, it may, therefore, be always omitted. The arcs H F, H_1F are drawn with radius = 2in., the length of the planimeter, from centres at the distance of H and H_1, from the axis. Practically, these arcs may be made a straight line, but the mathematical demonstration is that the arcs drawn to radius L, and equalising the + – + – + areas, has its ends horizontally apart a distance equal to the mean breadth of the diagrams, when L is twice the length of the cards. The horizontal distance H F, measured with the appropriate indicator scale, is, therefore, the mean pressure. The axis need not be drawn *accurately* perpendicular to the atmospheric line; square to the eye will be sufficient.

This explanation has been written, not because the instrument is of importance, but because the geometry of the problem is interesting, and because vague and erroneous statements have been promulgated regarding its accuracy.

ON THE SIMILARITY BETWEEN THE AFTER-GLOW OF THE GEISSLER TUBE AND THE FIRST GLOW OF SOLID BODIES.*

BY CARL KIRN.

The researches of H. F. Weber on the evolution of light-emission from glowing solid bodies have proved, as is well known, that the first visible light is not, as Draper formerly gave out, dark red, but "dark-fog-grey," which shows itself spectroscopically as a band in the yellow-green, to the eye the brightest part of the visible spectrum, and widens out on either side as the temperature rises. The temperature at which bodies emit this first-visible grey light is much lower than that at which the dark red glow begins, and is different for different bodies. The researches of Stenger and Ebert on the limits of visible light next showed that the phenomenon was conditioned by the different sensitiveness of the eye to the different colours, this sensitiveness being a maximum for that part of the spectrum where the band of the grey light is first seen. It was certainly to be expected *à priori* that generally in the case of luminous phenomena the same order of events would occur, those at extinction being the reverse of those on lighting up. I am not aware, however, that such an investigation has been carried out, so that the spectroscopic observations I have made on the so-called after-glow of Geissler tubes may not perhaps be altogether without interest.

The particular after-glow tube in these experiments was made by the firm of Dr. H. Geissler, of Bonn, and came indirectly into my possession. It had a bent serpentine shape, and was provided with seven globular enlargements. In the inside of the tube, especially in the enlargements, there were delicate flakey deposits, and a few specimens of colourless crystals that probably consisted of sulphuric anhydride.

The tube exhibited after an electric discharge had been passed through it, all the usual phenomena observed by Riess and Morren, the yellowish-white after-glow of the bulbs (the narrow parts of the tube glowed somewhat more feebly, and with a more yellowish-grey tint), lasted for more than half-a-minute in a completely dark room. The end bulb containing the negative electrode glowed more feebly, and went out the first, whilst the remaining six bulbs remained visible somewhat longer, and went out in succession from the negative to the positive pole.

Spectroscopic observations were made with a Desaga prism apparatus. Whilst the electric discharge was actually passing, the tube exhibited a line spectrum, which was most pronounced in the narrow parts of the tube, and the brightest line of which seemed to me, after comparison with a spectrum tube of my own making, to coincide with the nitrogen and carbonic oxide lines. The same spectrum is also clearly recognisable, at the commencement of the discharge, in the bulbs. But the moment the well-known nebulous glow makes its appearance in the bulbs the definition of the line spectrum diminishes, and assumes the character of a continuous spectrum in which the background is becoming brighter.

The feeble spectrum of the after-glow is continuous, without noticeable dark places, and occupies at first the entire space taken up by the previously mentioned line spectrum, but it shrinks tolerably quickly from either side (rather more from the blue than from the red) into a band lying between wave-lengths 555—495 $\mu\mu$, and this band vanishes more slowly diminishing in breadth, and gradually goes out. Nevertheless, the colour of this band is not the clearly defined colour of that part of the spectrum, but a characteristic pale yellow grey, which gradually becomes darker as extinction is approached. The place of the final tint corresponds almost with the E line of the solar spectrum, and coincides closely with the region of greatest brightness of the ordinary visible spectrum. The whole phenomenon of the extinction of the after-glow is, therefore, the exact reverse of what is observed to take place when solid bodies begin to glow.

Opinion is still divided as to what is the true cause of the after-glow of discharge tubes, nevertheless research seems to show that the phenomenon must be considered as the result of chemical modification of the contents of the tube, and as a chemico-luminous phenomenon. It is to be regretted that, owing to the nature of the experiment, it is impossible to investigate the beginning of the fore-glow owing to the previously-mentioned brilliant line spectrum interfering with the observation of the development of the feeble, continuous spectrum. However, one may very well conclude that the order of events on extinction is the reverse of that when the light is generated.

My observations seem to me chiefly worth communicating since they relate to light due to luminescence.

* *Wied. Ann.*, No. 6, 1894, p. 381.

LEGAL INTELLIGENCE.

Muirhead and Others v. The Commercial Cable Company (Limited).

It will be remembered that in the report of this case, which appeared in *The Electrician* of May 4th, it was stated that a day would be fixed for his Lordship to hear counsel's arguments upon the question as to whether or not the plaintiffs—who were the successful parties—were entitled to interest, and at what rate, upon the amount recovered! Judgment was recently delivered in favour of the defendants.

Mr. JUSTICE KENNEDY said that article 5 of the agreement, dealing with the question of time, fixed the royalty in these terms:—"The royalty, determined as above mentioned, shall be payable in London quarterly, and shall commence to run from the expiration of the first period of 15 consecutive days during which the inventors shall have maintained their said apparatus in good working order on the company's cables or cable, and transmission of the cables shall have been determined between the parties," after a realisation of an increase of 30 per cent. at least in the power of and then there was further provision. His Lordship said that, looking at the method of ascertainment of time as prescribed in that article, it seemed to him quite impossible to distinguish this case from the one decided in the Exchequer Chamber (Merchant Shipping Co., Limited, v. Armitage). For those reasons his Lordship said he must disallow the plaintiffs' claim for interest. Judgment would therefore stand for the amount claimed, less, as he understood it, the sum of £135 which had been paid into Court, and which the plaintiffs were entitled to take out.

Mr. POLLARD reminded his Lordship that there was another point on the question of interest, which did not depend upon the written agreement but upon the express claim in the writ.

Mr. JUSTICE KENNEDY said that upon that point he was quite clear that the fact of there being a claim and demand in a writ was not a demand within the operation of the section (3 & 4 Will. IV., c. 42, s. 28) which constitutes a demand. He was, therefore, against him on that point as well.

National Telephone Company v. Morris Brothers.

An action was recently brought in the Sheffield County Court by the National Telephone Company against Messrs. Morris Brothers, chemical manufacturers, of Doncaster, for £50, balance of rent due for telephone service. The defendants lodged a counter claim for £50 damages arising from the defective working of the telephone. It was not denied that the rent claimed was due under the contract between the parties, but it was held that plaintiffs were not, under the special circumstances, entitled to it.

Mr. WILKINSON, for the defence, said some time in the year 1889 his clients were approached by the Company with reference to putting up a private wire between their offices in Doncaster and their works at the village of Stockwith-on-Trent, 20 miles distant, and also a wire between the offices and the residence of Mr. Morris, the senior partner. When the contract was sent for signature, it was accompanied by a letter, in which the Company stated, amongst other things, "We guarantee that the communication between your offices and works will be absolutely satisfactory to you, and that any repairs, should there be any, will be attended to at once by the Company." It was on that strongly worded assurance that defendants signed the agreement in March, 1889. Although it was said the wire would be laid in a few weeks, it was 12 months before it was completed, and it was not until March, 1890, that the defendants were placed in possession of the service. From the very commencement they were subject to great annoyance, because of the imperfectness of the communication. In consequence of this, the Company allowed a deduction of £10 on the rental for the first year. During the succeeding three years the communication continued to be most unsatisfactory. Complaints were constantly made to the Company; in fact, no less than 118 letters calling for a remedy were sent, but with no result. About two years ago the

Digitized by Google

Company put up some wires for other parties on the poles used for defendants' private wires, and this added to the confusion. There was (counsel said) no doubt the work carried out for defendants was unskilfully done. The Company had almost continuously sent men to effect an improvement, but they did not succeed, and defendants' business had been interfered with. The contract was made from a company point of view, and defendants, as business men, would not have signed such a one-sided document unless they had had some distinct assurance from the Company, such as that contained in the letter, that the service would be satisfactory, and counsel contended that the guarantee became part of the contract.

A number of witnesses were called on behalf of defendants, whose evidence bore out counsel's statement, and it was finally agreed to adjourn the further hearing to a date to be arranged.

Re the Printing Telegraph and Construction Company of the Agence Havas.

In the High Court of Justice, on Tuesday, Mr. Justice Kekewich commenced the hearing of a motion *ex parte* Elvey and two actions of the Company v. Lord Windsor and Lord Windsor v. Ratcliffe. The case, like many others recently tried, shed a glaring light on the peculiar ways of the company promoter.

Mr. WARMINGTON, for Mr. Elvey, explained that his client was seeking to have the register of the Company rectified by the removal of his name therefrom in respect of shares. Lord Windsor had brought an action against the Company to be similarly relieved, and the Company brought a cross-action against him for calls. The facts in the two cases of Elvey and Lord Windsor were to some extent the same, and it had been agreed that, as far as possible, the evidence should be regarded as applying to both. In the early part of March, 1893, Mr. Elvey was introduced to Mr. Beyfus, solicitor to Messrs. Ratcliffe and Viben Smith, the owners of an American patent and promoters of the defendant Company, whose object was to raise in this country capital for the development and employment of an invention for which a Mr. Wright had taken out, in France, a patent for printing in columns news transmitted by wire. On March 17th Messrs. Slaughter and May, solicitors, who were registering and forming the defendant Company, in London, wrote announcing the appointment of Mr. Elvey as assistant manager in Paris, at a salary of £250 a year, subject to three months' notice on either side. The Directors, the letter stated, were willing, and intended, to proceed to allotment as soon as *bonâ fide* applications for £40,000 of shares had been subscribed. Mr. Elvey had been asked, as a means of procuring the appointment, for an underwriting letter to secure a subscription of 1,000 shares at £5 each; and he made it a condition of giving this letter that he should be appointed, but that his colleagues, who were also to subscribe underwriting letters, should be *bonâ fide* subscribers, and capable of performing their contracts. The learned counsel quoted the details of an agreement between Ratcliffe and Smith and the defendant Company, which recited that a company had been formed, with a share capital of £115,000 in £5 shares, for acquiring the rights and using the inventions relative to printing telegraphs; it also recited an agreement between the American company owning these rights and the vendors, who were to subscribe, or procure subscriptions for, £40,000 of the share capital of the Company. The Directors had also agreed to appoint Mr. Elvey as assistant manager for one year, subject thereafter to three months' notice on either side. So far, however, as could be traced by the minute-book, no such meeting was held on that day. Meantime Mr. Elvey had signed the underwriting letter, and given it to Beyfus and Beyfus, his solicitors, but wired them not to give up the guarantee, but the wire was received after the letter had already been parted with. Messrs. Beyfus were not authorised to part with the letter until the two conditions of Mr. Elvey's undertaking had been complied with, and on receiving an allotment letter from the Company on April 6th he wrote to the secretary repudiating and refusing to accept it. Apart from these facts, the Company, by a resolution of May 27th, rescinded their contract with Ratcliffe and Smith, therefore the Company could not both rescind Ratcliffe and Smith's contract and claim under it. At the time of the commencement of these proceedings there was no legal register of shareholders on which applicant's name could be placed, and from which, therefore, he could be struck off, as he had now formally to ask should be done. Applicant likewise charged such misrepresentation in the prospectus and dealings of the Company as entitled him to repudiate any alleged contract so tainted. He further objected that of the underwriting letters of £52,000 reported to applicant's solicitors on March 23rd, as having been obtained by the Directors, some £25,000 had been subscribed partly by persons of whom some could not be found, and partly by others who were unable to meet any calls that might be made on them. Among the grounds on which the application was based was that the prospectus, as a whole, was calculated to lead people to believe that the invention which the Company held was a monopoly, which was not true, the French Government having in 1892 granted to the Agence Dalziel a concession or authority of exactly the same nature and terms as they granted to the Havas Agence.

Sir RICHARD WEBSTER, on behalf of the defendant Company, said he had advised his clients that, apart from the merits of the case, it raised intricate points in company law which, if threshed out, would consume much time and such heavy costs that victory would be little better than defeat. The Company had some 20 machines at work, and between 20 and 30 more were now on their way from America, and there was every reason to believe that it would prove a success, whereas if litigation should be continued it might result in disaster. He had therefore advised his clients that if any reasonable arrangement could be arrived at it should be done, the more so as there were other parties awaiting the issue of these actions and threatening other proceedings. In these circumstances he asked his lordship to give the parties, say, a week to review the position, and see whether an arrangement could be arrived at, to the great saving of expense, if of nothing else.

This was ultimately agreed to, and the case was adjourned for a fortnight.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"INVENTIONS, RESEARCHES AND WRITINGS OF NIKOLA TESLA," by T. Commerford Martin, may be obtained from the Publisher of *The Electrician*, and a copy will be forwarded post free on receipt of 16s. 6d.

"HOW TO WIRE BUILDINGS."—Copies of this work, by Augustus Noll, will also be sent by the Publisher post free on receipt of 6s.

TENDERS INVITED.—The Local Authority of the burgh of Ayr require tenders for the supply and erection of plant and apparatus required for their electric lighting scheme. Tenders can be for any section or sections of the whole. All necessary particulars, specification, &c., can be obtained at the offices of Mr. Robert Hammond, Ormonde House, Great Trinity-lane, E.C., on and after to-morrow (Saturday); and tenders must be sent in to Mr. A. G. Young, Town Clerk, the Council Chambers, Ayr, not later than Saturday, June 23rd. Further particulars are given in our advertisement columns.

——— The Acton Local Board invite tenders for the transfer of their Electric Lighting Provisional Order. Tenders have to be sent in by 6 p.m. on June 5th.

——— The Inspectors for lighting the town of Alford (Lincs.) are prepared to enter into a contract for lighting the town by gas or other illuminant. Tenders must be sent in to the offices of the Inspectors, West-street, Alford, by June 9th next.

——— The Coventry City Council invite tenders for the erection of an electric lighting station, which must reach the Town Clerk by June 13th.

——— The Grimsby Urban Sanitary Authority require tenders for the lighting of the public streets of the borough for one year. Further information can be obtained of the Borough Surveyor; and tenders must reach the Town Clerk by June 8th.

——— Mr. H. N. Mollwo, 72, English Quay, St. Petersburg, is desirous of obtaining from leading electrical firms estimates for supplying electromotors for use on the tramways in the Russian capital.

——— The Directors of the North-Eastern Railway invite tenders for telegraph apparatus, telegraph wire, and line stores for the six months ending December 31, 1894. Tenders must be in by noon on Tuesday next.

——— The Director-General of French Posts and Telegraphs requires tenders for the supply of 350,000 kilogrammes of bronze and copper wire of high conductivity and 4,000 tinned copper connectors (in eight lots). Forms of tender may be obtained from the Direction-Générale des Postes et des Télégraphes (Division du Matériel et de l'Exploitation électrique, 3e Bureau), 103, Rue de Grenelle, Paris, up to June 3rd, and tenders will be received till 11 a.m. on June 14th.

Digitized by Google

Tenders Accepted.—The Halifax Corporation have accepted the tender of Messrs. W. H. Bailey and Co., Albion Works, Salford, for the supply of steam pumps for the sum of £1,168.

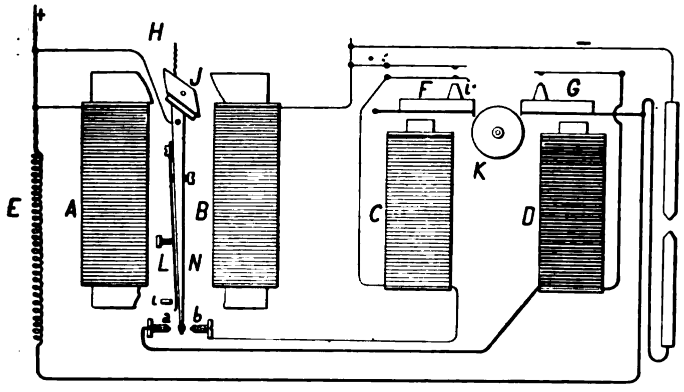
Liquidations.—A meeting of the shareholders of Anders, Elliot and Chetham-Strode (Limited), which is in voluntary liquidation, is to be held at Mr. F. H. Ebsworth's 1, Arthur-street East, London, E.C., on July 12th, at 3p to receive an account of the winding-up.

Removal.—Messrs. Bennett and Druce are removing from 44, Fishergate, Preston, to larger and more convenient premises, at 30, Winckley-square, Preston.

"Snowflake" Composition.—Mr. V. Fabris informs us that this composition has recently been successfully applied to a large number of incandescent lamps at the Oxford Music Hall and at the billiard rooms of the Bedford Hotel, Tottenham Court-road, W.C.

Mechanical Ventilation.—Messrs. Baird, Thompson and Co. have received information that the installation of their mechanical ventilation process in the steamship "Zweena," for Messrs. Forewood Brothers and Co., has resulted so satisfactorily that it is intended to extend the system to the remainder of Messrs. Forewood's fleet. The system is also adopted by the Neptune Steam Navigation Company, and also at Hull by the owners of a large fleet of steamships. A new illustrated catalogue describing the system can be obtained at the Company's offices, 159, Queen Victoria-street, London, E.C.

The "Cock" Arc Lamp.—A successful attempt to design an arc lamp be used in places for which incandescents only have been employed has been made by M. Cadiot, 44, Rue Taitbout, Paris, whose "Cock" lamp is illustrated in the accompanying figure. Between the poles of the electro-magnet A B, wound with thin wire of 500 ohms resistance, is pivoted an iron armature, J, to which is fixed a lever, N. The solenoid C, also wound with wire of the same resistance as the electro-magnet, draws the carbons close to each other, when N makes contact with *b*, while the solenoid D, wound with



thick wire of a resistance of 1·5 ohms, separates them when N, making contact with *a*, puts the lamp in circuit with the resistance E. The solenoids actuate two arms, F and G, which move an endless screw, tangential to a wheel round which is a chain attached to the carbon holder. The current being switched on, the electro-magnet A B attracts the movable armature J, and the lever N, making contact with *b*, the solenoid C is put in circuit, and its armature F causes the carbons to come into contact. The difference of potential at the poles of the magnet becoming very small its force is overcome by the opposing spring H, and N, therefore, makes contact with *a*, so that the current is diverted to the thick-wire solenoid D, the vibration of whose armature, G, continues until an equilibrium is attained between the attraction produced by the magnet A B and the action of the spring H. The difference of potential at the poles of the magnet increases as the carbons consume, and the action goes on as before—the lever N makes contact with *b*, and the solenoid C is put in circuit. To prevent sudden recoils, which may be caused by the impurity of the carbons or by the instability of the armature J, the lever N is mounted a spring, L, whose pull is added to that of the spring H, but which is released before the contact with *b* brings the carbons together. The lamp is small, and, it is claimed, takes but little current. The candle-power may, it is stated, be varied from 100 c.p. to 400 c.p., by the aid of a rheostat, operated according to whether more or less light is required. A suggested advantage of this lamp is that, owing to the recoil movement, it can be successfully used in installations where the dynamo is driven by an engine subject to variable loads, and its small size allows it to be fitted into electroliers, pendants, &c., as well as for public lighting.

New Post Office Telephone.—The Consolidated Telephone Construction and Maintenance Company, of 109, Farringdon-road, London, E.C., issue a circular illustrating their new form of Post Office telephone, which is devised under instructions given by the chief engineer and electrician to the British Post Office, and is manufactured by the Company. The circular also illustrates a new form of transmitter, which can be used on the existing sets of call bells and receivers, and can also replace the Blake transmitter. The circular and other particulars can be obtained on application.

Leakage Indicators.—Messrs. Nalder Brothers and Co. are now making Major Cardew's new recording leakage indicator for high-tension alternating circuits.

Morris's Combined Ammeter and Voltmeter.—This instrument consists of a strong brass case 8in. in diameter, with four terminals; two small terminals are used for the volts, and the two large terminals for the amperes. It has two hands or pointers, on each of which is a disc suitably lettered. By this plan it is claimed that there can be no mistake in the readings. The instrument is patented by Mr. W. R. Morris, of Birmingham.

Domestic Electricity.—The Westminster Electric Supply Corporation have just issued a neatly-printed circular giving particulars and illustrations of a variety of cooking and heating apparatus. It does not appear from the circular that the Company are prepared to supply the apparatus, the cost of which is set out in the circular. The offer made by the Company is to supply current for cooking and heating purposes at 4d. per unit after July 1st through a separate meter.

Acton.—The Works Committee of the Local Board have reported that the negotiations with Mr. Medhurst for the taking over of the Electric Lighting Order are at an end, Mr. Medhurst finding that, with the conditions laid down by the Board, he was unable to float a company to take over the Order. It was decided to invite tenders for the sale of the Order, and advertisements are appearing, as stated elsewhere.

Belfast.—The Board of Guardians having considered the question of substituting electricity for gas in the workhouse, have decided that, although the former must be considered the more healthy light for hospital purposes, the increased cost of £96 per annum which would be entailed prohibits its adoption at present.

Blackburn.—Mr. Thomas Barton writes that—a note in our last issue, stating that the contract for lighting the Free Library and Museum by electricity had been let to Mr. J. McLellan, is inaccurate. The current for the lighting of this building is to be supplied from the Corporation mains, and the internal wiring is already completed, having been carried out by Mr. Barton some time back.——It is stated that it will be necessary to hold another Local Government Board inquiry into the application of the Blackburn Corporation to borrow money for the erection of an electric lighting station.

Blandford.—Many years ago this town was destroyed by fire, and it is not until recently that a satisfactory water supply has been organised. This is now being done, and powerful oil engines are being fixed for pumping purposes. Mr. E. R. Dale, of Sherborne, Dorset, has suggested lighting the town by electricity. As a commencement, the Crown Hotel and the public vehicles of the place have been provided with electric lamps.

Bridlington.—The Local Board have decided to light up the sea-front from the north end of the Prince's-parade to the north end of the Beaconsfield Sea Wall by electricity at an estimated outlay of £275. The Prince's-parade has been lighted electrically for some time past, and has been proved such a success that the Board have decided to extend the electric lighting.

Chelmsford.—An application from "a London company" to establish a telephone exchange at Chelmsford in connection with the proposed line between London and Norwich was at the last meeting of the Town Council referred to the General Purposes Committee. The line is estimated to cost £2,000.

Church and Chapel Lighting. — The Calvinistic Methodist Chapel at Llandinam is now lighted by electricity. The Parish Church of St. Deinol, Itton, is also now lighted electrically.

Church Gresley.—The proprietors of the Cadley Hall Colliery have decided to adopt the electric light, and have placed the contract with Messrs. Hewes and Geary.

Chelsea (London).—Mr. T. W. E. Higgins, Surveyor to the Chelsea Vestry, has issued a report on the dust destructor scheme at Kensal Town, and the advisability of utilising the heat for public baths or electric lighting. He reports that, in response to his invitation for applications from several leading firms of dust-destructor manufacturers, four schemes were submitted, by (1) Messrs. Horsfall, (2) the Municipal Appliances Company, (3) Messrs. Manlove Alliott and Company, (4) Livet's British Steam Generator Company. As regards utilising the heat for electric lighting, Mr. Higgens reports that there are about 200 lamps

Digitized by Google

scattered over seven miles of streets, and the laying of cables to cover this extensive area would be an exceedingly costly proceeding, resulting in much waste, therefore, the idea of lighting the street lamps in this district from the heat generated in the destructor, is out of the question. It is pointed out that the Vestry have not yet obtained a Provisional Order for the supply of electric current, and that this would first of all have to be provided for. The demand for current for private lighting would be small, and, therefore, Mr. Higgins is not in favour of this scheme.

City of London.—The Commissioners of Sewers have just issued a scale of fees to be paid in respect of services to be rendered by the electrical inspector within the City boundaries. The scale includes fees for testing under various conditions, the fees ranging from 2s. 6d. to £1. 10s. Any objection to the scale must be lodged before June 22nd.

Dewsbury.—The electric lighting works here are making satisfactory progress, and evidence is not wanting that the light will be fully patronised by the principal residents and tradespeople. Several of the latter have commenced wiring their shops, offices, warehouses, &c., so as to take current from the Corporation mains as soon as ready.

Dover.—An electrical exhibition, organised by the Dover Electricity Supply Company (Limited), was held last week in the Connaught Hall under the supervision of Mr. Alfred Matthews, and proved of considerable interest to a large number of visitors.

Dundridge.—Messrs. Veale and Co., of St. Austell, have just completed an extensive installation of the electric light for Mr. R. Harvey, of Dundridge, near Totnes, whose mansion is now lighted by 153 incandescents of 8, 16, and 32 c.p. The plant consists of a Crompton dynamo, driven by a 7-h.p. Crossley oil engine, and includes a battery of 53 Crompton-Howell cells.

Exeter.—The Devon Standing Joint Committee have accepted an offer of the local electric light company to instal the electric light at the Central Police Station, at a cost of £55, the annual cost of maintenance being £39, as compared with £30. 18s., the present cost of gas.

Hanley.—The arrangements for the public lighting of this town by electricity are nearly completed, and the light is being used in many of the principal shops and in the Free Library. Many of the street lamps are erected, and have been twice tested, and in each case found to be in perfect working order.

The Hartlepools.—In reference to the electric tramways at West Hartlepool, it is now, we understand, proposed to form a local company to carry through the undertaking, a start with which will, it is expected, be made within the next few weeks.

Hospital Lighting.—The electric light has been introduced into the Ophthalmoscopic room at the Moorfields Ophthalmic Hospital, to the great advantage of both surgeons and patients.

Hotel Lighting.—The new Palace Hotel, High-street, Kensington, London, W., which has cost over £200,000 to construct, is 120ft. in height, with a frontage of 224ft., and contains upwards of 350 rooms, has been lighted throughout by electricity.

Howth Tramway.—A meeting has been held to oppose the proposed electric tramway to the Hill of Howth, a suburb of Dublin, one of the principal objections being that the line would disturb the "peaceful beauty which constitutes the chief attraction of the Hill." It was stated by one of the speakers that the district was already invaded by large numbers of people from Dublin, "and it was desirable that Howth "should be protected from further invasion." Two of the principal proprietors of the district, Lord Ardilaun and Lord Howth, are in favour of the scheme, provided certain conditions laid down by them are agreed to.

The Lighting of Model Dwelling Houses.—In the House of Commons on Tuesday, in Committee on the London County Council General Powers Bill, it was proposed by Mr. Naoroji that a new clause be inserted compelling the owner of any buildings designed for use as flats or tenements, in which any staircase or passage is used in common by the occupants, to keep the same lighted from sunset to sunrise to the satisfaction of the Lighting Authority of the parish or district in which the tenement or building is situate, and providing that the Lighting Authority for the district should, by agreement with the owner, undertake the lighting, and to supply the necessary lamps and fittings, &c., on terms to be agreed upon. On the part of the County Council the clause was opposed, and the Council further withdrew the lighting clause as it originally stood in the Bill. It was pointed out by Sir Julian Goldsmid that both the original clause and the proposed new clause would involve an outlay on the part of the Model Dwellings Association of £10,000 a-year. The new clause was by leave withdrawn.

The Lighting of Newspaper Offices.—Very few newspaper offices in the neighbourhood of Fleet-street now remain unacquainted with the advantages of the electric light. The offices of the *Scotsman* are now to be lighted electrically, the work having been entrusted to Messrs. John Bolding and Sons, of Davies-street, London, W.

Lowestoft.—Mr. G. H. Hamby, the borough engineer of Lowestoft has compiled a set of very interesting tables of information obtained from cities and towns throughout the country as to the comparative cost of lighting by gas and electricity. The information has been specially prepared for the use of the Lowestoft Town Council, and, as indicated in our last week's issue, is to be circulated amongst the members of the Council. Seven columns in the Table are devoted to information concerning the lighting by gas, and nine columns to lighting by electricity. The Tables give information which will doubtless enable the Town Council to arrive at a speedy decision as to the advisability or otherwise of applying for a Provisional Order for lighting the district.

Mill Lighting.—The electric light is to be introduced throughout the extensive Brookside Mill at Leigh, the property of Messrs. Gamble and Smith.

——— The flour mills at Bolton, Lancashire, owned by Messrs. Ormrod, Hardcastle & Co. (Limited), are to be lighted throughout by electricity. The plant will consist of a dynamo capable of lighting 1,300 lamps, requiring about 120 h.p. to be driven at slow speed from one of the mill engines. There is to be in addition a small pilot dynamo capable of lighting 100 lamps. The contract has been let to Messrs. Bennett and Druce, the designs and arrangement of plant being carried out by Messrs. Shepherd and Watney, of Leeds.

Newcastle-on-Tyne.—A Special Committee of the Corporation have resolved to report to the City Council that it is desirable for the Corporation to be in a position to supply the City with the electric light.

Norwich.—Notwithstanding the opposition of the Rev. G. H. Cooke, who contended that the money would be better spent on books for the library, the recommendation made by the Committee of the Norfolk and Norwich Library that electric light should be substituted for gas has been carried by a large majority. A report from Gurney's Bank that a considerable money saving had been effected by the substitution of electricity for gas quite upset the opponents of electricity.

Presentation.—At the Claybury Asylum, on Wednesday last, Mr. Ross Cotton, A.I.E.E., was presented by the electric lighting staff with a silver-mounted walking stick, cigar case, and an illuminated address on the occasion of his leaving the station.

Preston.—A Parliamentary Committee, presided over by Sir James Kitson, has, during the week, had under consideration the Bill promoted by the Preston Gas Company authorising the construction of additional works, the raising of £2,000,000 of further capital by shares and £50,000 by loan, and the extension of the Company's operations by power to apply for an electric lighting Order. The Bill is opposed by the Preston Corporation and by several of the principal landowners in the district. Mr. Green, Secretary and Manager of the Gas Company, in the course of his examination, said that he did not think the Electric Lighting Company at Preston, which had prejudicially affected the Gas Company's business to the extent of about 10,000,000ft. a year, would be likely to suffer from the extended powers asked for by the Company, as they now had all the principal customers in the town.

Provisional Orders.—The Electric Lighting Provisional Orders for Buxton, Chesterfield, and Barrow, have passed through Committee, and have been ordered to be reported for third reading. The Electric Lighting Orders lodged by the Shrewsbury Electric Light and Power Company (Limited) for the lighting of Shrewsbury and district, by Messrs. J. C. Howell (Limited) for the lighting of Aberdare, by the Yeadon Local Board, by the Wakefield Corporation, and by the Birmingham Electric Supply Company (Limited), have all passed the examiner of the House of Lords and stand for second reading; and the Provisional Order of the West Hartlepool Town Council has been read a third time and passed, subject to the Royal assent.

Queen's Birthday Illuminations.—Several novel devices in combination with the electric light were noticeable in the illuminations in the West End of London in celebration of the Queen's birthday on Saturday last, but owing to the steady downpour of rain, little or no attention was bestowed upon them.

Salisbury.—The Town Council have unanimously assented to the application of Mr. H. Gramshaw, on behalf of the Salisbury Electric Light and Supply Company (Limited), giving their consent to the Company's application for a Board of Trade licence to supply the district with electric current.

Sheffield.—The Sheffield Electric Light and Power Company have commenced laying their electric lighting mains westward, and this district is expected to be connected up during the coming autumn.

Digitized by Google

SHOREDITCH (LONDON).—The Vestry are proceeding with the arrangements for the purchase of the Pitfield-street site upon which the electric lighting central station is to be built in conjunc- with the dust destructor, public baths, library, &c. This piece of land is to cost £33,000, and the whole scheme will cost nearly £100,000.

TAUNTON.—We have received the following from Mr. Harold W. Couzens, borough electrical engineer, in reference to a Trade note in our last issue:—"Just a line to correct a small error in your Note *re* Taunton in this week's issue. It was my quarterly report to the Town Council that you have quoted from. I subjoin a little further information from it which may be of interest. We have fixed the 50 H.P. Bumsted and Chandler engine and 30 unit alternator, and are working them regularly during the hours of light load. No. 1 transformer sub-station is now in full working order, and we have now 960 8-c.p. lamps connected to the low-tension cable. We are erecting the steam drums and piping, and have raised steam in the new (105 H.P.) 'Economic' boiler."

WESTON-SUPER-MARE.—The Town Council have resolved that the Electric Lighting Committee be instructed to choose an engineer to report on the whole question of electric lighting, electric tramways, and refuse destructors, the fee to be 50 guineas.

WORCESTER.—It has been decided to charge 5d. per unit for electric current, subject to a discount of 5 per cent. for cash, 3 per cent. on accounts of from £25 to £50, 5 per cent. from £50 to £100, and 10 per cent. from £100 upwards. It was the opinion of many members of the Corporation that 6d. should be the minimum charge, but the casting vote of the Mayor decided the matter.

COMPANIES' MEETINGS AND REPORTS.

West Coast of America Telegraph Company (Limited).

The 17th ordinary general meeting of this Company was held on Tuesday at Winchester House, Old Broad-street, under the presidency of Mr. J. Denison Pender.

The SECRETARY (Mr. Fred. L. Robinson) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: Before I move the adoption of the report I have one painful duty to perform—in having to record the death of Mr. Henry Roberts. He had been a member of this Board for some time, and I think he took the chair at a meeting which was held not very long ago. Mr. Roberts was a member of one of the leading firms of shipowners, and was, therefore, able to gauge very well the commerce of the country. His death has been a severe loss to this Company, and a personal loss to both Mr. Walters and myself. I will now give you some further information on the various points mentioned in the report. The gross receipts, you will see, are £7,122 less than in the previous year; but in 1892 the receipts included the sum of £4,782, which was received from the Chilian Government, you will remember, in settlement of the Company's claim for damage during the Revolution in 1891, and in that year also the rates of exchange both in Peru and Chili were much more favourable than they have been since. The sterling value of the telegrams received last year was £13,155, against £14,832, showing a reduction of £1,677, which is attributable entirely to the decline in the rates of exchange. The total number of words carried by us in 1893, although they brought in less revenue, as I said, on account of the exchange, was 131,700 in excess of those carried in 1892. If the exchange had remained the same we should have had a very considerable increase in our revenue instead of a decrease. General expenses in London are pretty much the same as they were in the previous year. The general expenses at stations are also about the same, the total amount being rather less than in 1892. The working expenses of the repairing steamer "Retriever" showed a reduction of £1,021 as compared with those of the previous year. This item of course varies. If there are a good many breaks, and the steamer is employed, it means more expenditure for coal and wages, because when the vessel is in harbour she is not fully manned, whereas when ordered out to effect repairs she has to get hands from the shore to a great extent. It is, therefore, hardly fair to look on this item, although it is a considerable one of over £1,000, as being really a reduction in the expenses. I think myself that the item ought to be spread over a period, because next year we might find the figures—although I hope it may not be the case—compare unfavourably with those of last year, when we had little work to do in the way of repairs. Salaries and wages are about the same. The renewal charges for last year amounted to £2,720, as against £3,669 in 1892, being a reduction of nearly £1,000. I will now give you some particulars as to the question of exchange. The decline in the rates of exchange is a most serious matter for the Company, as we have to pay our staff in sterling, and being confronted by competition, we cannot raise our rates. As an illustration of what we have to contend with, I may mention that the rate per word between Valparaiso and Iquique, which is the busiest cable circuit we have, averaged last year only 3½d., and for this we have to provide and maintain a cable 913 knots in length. The tariff for messages over this cable is 25 cents. currency per word. The rate of exchange in Chili was 17d. at the beginning of last year and 12½d. at its close, the traffic being consequently worth to us 4¼d. per word at the former rate of exchange, and 3$\frac{1}{10}$d. per work at the latter rate, the difference between these two rates being about 28 per cent. against us. This is absolute loss to us, which at the present time we cannot possibly make up. That brings this matter more forcibly before you, together with what I have already told you about the number of words we have carried this year as compared with last year, although the revenue is smaller. Another item in the accounts, which is much heavier this year is the legal expenses. In former years they have been very small. This year they amount to over £100, but this is in connection with the formation of the Pacific and European Company, of whose paid-up capital the West Coast of America Company hold one-fourth. That Company, as I told you at the last meeting, really connects us with the outside telegraph companies again, because we were debarred until the Pacific and European line was built and open from communicating with them, as our adversaries, who had the competing cable on the West Coast, also had the line across the Andes. Therefore if we wanted to send any messages they had to go into the hands of those we were competing with, and they did not assist, but rather the reverse. During the year the shore ends of the Antofagasta cable were renewed, and a new land line was constructed between the station at Valparaiso and the northern cable hut, the cables and land lines being kept in the most perfect state of repair. At our last meeting, if you remember, I mentioned some particulars to you about the Talcahuano cable, which was then, I believe, on its way out. This cable was laid and has been opened now for traffic for some months, and the results are certainly satisfactory. It was opened for traffic on October 1st, as were also the land lines connecting the port of Talcahuano with the City of Concepcion. The total cost of the work has been £29,700. The traffic over the line is satisfactory at the present time, and it is certainly likely to increase. There is no doubt that the addition to our net income will be materially increased by this. Originally Valparaiso used to be the one main channel of export and import for the whole of Chili, but that has ceased to be the case to a very great extent. A good deal of the business formerly transacted there is now done for the mineral district of the north in Iquique, and the agricultural district of the south does very nearly all its business at Concepcion. I think it will certainly form an important addition to our cable. At the time we had to do this work, last year, when the Pacific and European lines were not open, and we were living really on our reserve fund, it was not a very pleasant thing to have to undertake an expenditure of about £30,000, knowing that we were losing money at that time, and that we should want all our resources. However, I think your Board would have been wanting in energy and foresight if they had not undertaken it. If we had not done it I am perfectly convinced that others would have stepped in. We, therefore, resolved to carry it out, and the work has been successfully done, chiefly by our own steamer. We sent the cable out in a sailing ship, which we were able to fill with coke, thus really very materially reducing the cost of freight, the coke having sold very well on the other side. I now come to perhaps the most important part of the work last year, the opening of the Pacific and European Company's line. This new line from Buenos Ayres to Valparaiso was opened for traffic on March 19th this year. In my speech last year—I just now referred to it—I see that I said it would be open in three months. At that time I thought that three months was giving an ample date for the work, but there were several causes which occasioned considerable delay. We had, for instance, to get the wayleaves, and there were many other causes which I cannot actually give you here. The share capital of the Pacific and European Company is held by the companies chiefly interested in the traffic going over its line, and the principal and interest of the debentures are guaranteed by the Brazilian Submarine Company, and this Company jointly. You will be glad to know that the service is giving thorough satisfaction to the users of the line. Messages are carried very quickly, the actual time which they take between the West Coast of South America and London being not over an hour, and sometimes considerably less. I do not think that can be beaten, and it is a very fine record. The line is also worked throughout from London to Lima by English operators. I cannot at this meeting give you any information as to the revenue we shall derive from this new line. I think we must wait a little longer for that. It has only been opened for two months, and I have always found in considering the question of traffics that two or three months' working is of no use to take for a record. There are various seasons in these places when trade is very much larger than at other times, and therefore one might give you a misleading idea of the traffic, for the time might have been one of slack trade when it was carried, or it might have been a time when the traffic was active. It is better to wait for six months—or better still, for twelve months—before quoting figures as to revenue I am, however, able to say that the traffic is very satisfactory, and I am pleased with the revenue we are receiving. I may, perhaps, say a little more on this point owing to my interest in the Eastern Telegraph Company, running in connection with this line as far as Lisbon, and my connection with the Brazilian Submarine Company, which carries the messages on to South America, and thence across the Pacific and European Company's system on to our West Coast system. The Eastern Company here is naturally the collecting ground, and I can assure all the shareholders that this traffic is being very energetically worked up, thanks to

Digitized by Google

the officials in the Eastern Company. I receive reports constantly about it—sometimes daily, and at any rate every two or three days, and we are canvassing everyone individually who sends messages. It is very seldom that I use the word "glad" in reference to breaks; but I am glad to say that we have had one or two breaks since the line was open. The reason why I use the word "glad" is this: it is all very well to lay a land line, which can be done without much difficulty; but when a break takes place you see the actual value of a land line. If the organisation is good the stoppage of traffic lasts a very short time: if the organisation is not good, and the men are not on the spot to repair a break, you may be down for many days. I am glad to tell you that the breaks we have had have all been put right, wherever they have taken place, in a very few hours. There have been three breaks over the line I think that what I have said will prove to you that the organisation is perfectly good. I do not see the slightest difficulty now in keeping this line in a very efficient state; and if the senders of messages are satisfied with it, there is no question about our not only keeping, but daily increasing the traffic carried by it. It stands to reason, I think, that anyone having a message to transmit would send it by Brazil, and the quickest way. To go to South America across the North Atlantic, and then through America and down the other side, is a roundabout way—at all events, it looks so on the map. I think that I have now put before you all the different points that had to be noticed. I might add that we have changed our offices, and have come into Winchester House. That is a great advantage, because the companies we work with have their offices here also, and I think that the more we can all bound up together the more we shall add to our strength. As regards the rent of our new offices we are on the right side, for the amount is a little less than it was before. I shall now be very glad to answer any question that may be put to me.

Mr. T. R. PACE said that the Chairman had given the meeting so much information that he had not left the shareholders many questions to ask. He thought, however, that they would like to hear a little more as to the time when the Directors thought they would be able to afford them information as to the kind of business they were going to have over the line again. It was not quite like making a new business, of course, but rather the gathering together again of business which had been taken from them. He thought it was rather too long to wait until May, 1895, before they could learn whether they were likely to have any dividend or not. They accepted the Chairman's broad statement that the new connection was working favourably, but the sooner they could have their monthly traffic returns printed the better he thought it would be. The Chairman said that these countries had their slow and their active times, but he had not told them whether the new line was opened at an active time or not. They had suffered for some years in going without a dividend, but things now looked hopeful. The sooner they could have figures to show that they had got on a paying basis again, the more satisfied the shareholders would be.

The CHAIRMAN: I do not like to pledge myself to any figures, for I think it is dangerous to do so. As regards one question which has just been asked, the busiest time out there is, I believe, from September to March, and we opened on March 19th. You may therefore say that we got to work at the slack time. I would give you any figures that I could, but I myself have always found, as I said before, that figures to a great extent are of very little good and are misleading unless one can go on anything substantial. We cannot do that in regard to these figures. We have opened a new line. Remember that you had before one line carrying this traffic, but now it has to be divided into two, there being two lines. All I can promise you is that every endeavour will be made to increase the traffic. I have no fear myself as to the result. I have watched the matter very closely. I am connected with the Eastern Company, and it is my duty on behalf of that Company, as well as on behalf of this Company, to watch the traffic and to get it, and I myself am exceedingly pleased at the way we are getting it. And not only that. In many instances merchants will say, "we will try you, and see your time, and how you can carry a message," and I do not know of a single instance where a merchant has tried us and has left us. I will not give you any figures yet, because they might be misleading. I hope we shall very materially increase the traffic we are now getting, which is very good.

Mr. LAMONT inquired whether a common agreement could not be come to between this Company and its adversary by which the rates might be revised. If they received 4d. or 6d. a word twelve months ago, why should they now receive only 3d. a word? He supposed that their adversaries felt this reduction the same as this Company did.

The CHAIRMAN: Before this line was built the antagonism to us was very severe. They did all they could to thwart us, but since the line has been built we have, I think, carried on a pretty honourable competition. I hope that that will continue, and if it does I think it possible that we may eventually come to some terms with them on certain points, one of which is the exchange question as it affects our revenue. We have mooted the point, but they do not seem inclined to come to any terms with us yet, although I believe they have not absolutely refused to do so. However, your interests on that point will not be neglected.

Mr. DYETT said he thought they ought to meet together every six months, or to get a report once in six months, so that they might know how they were going on.

The CHAIRMAN: I have not been long in this Company, but I believe it has always been the rule to meet once a year. We shall be quite prepared to give you a report, or to meet you as you suggest. It is a pleasure to me to meet the shareholders of any company that I am connected with, but you must remember that our adversaries watch what we are doing pretty closely; and by means of questions which might be put, and that sort of thing, opponents sometimes get information which it would perhaps be best for one's own interests that they should not know. As far as I am concerned, the more the shareholders know about the Company the better I am pleased. I am satisfied that everything is being done that can be done to work up the traffic, and to bring the Company back again into a dividend paying position. In further reply to Mr. Dyett, the Chairman added: I always like straightforward opposition, for it does us all good, but I do not like anything that goes behind our backs in connection with rebates, and things of that kind.

Mr. LAMONT said he thought it might be possible for the Board at the end of six months to issue a circular to the shareholders, stating the position as regarded the traffic; but it was evident from what the Chairman had said, that a six months' report would be misleading, because they had now entered on the dull season, and, probably, in an active season the receipts might be doubled.

The CHAIRMAN: I have often seen that, but we will consider the question of presenting you with a short report in six months' time. The Company has been in a transition state, but we hope to get back our traffic now. For the last two or three years we have been doing nothing. If no other shareholder has any question to ask I will move—

"*That the report and accounts for the year ended December 31, 1893, now presented be received and adopted.*"

Mr. FREDERICK WALTERS seconded the resolution, which was carried unanimously.

The CHAIRMAN then proposed the re-election as a Director of Mr. Frederick Walters, who, he said, had a very intimate knowledge of the West Coast of America, having spent many years of his life there, and being connected with a firm doing business there. Mr. Walters was, therefore, a very important Director for their Company.

Mr. PACE seconded the motion, and said he thought they were very fortunate in having a man of Mr. Walters' experience on their Board. The Directors had had to contend against very adverse circumstances, but he felt sure that everything had been done by them that was possible. He considered that they ought to notice the courage of the Board in undertaking the construction of the new line referred to in such adverse circumstances. To make a new line at a cost of £30,000 at a time when they had been practically living on their reserve fund showed great courage and hope in the future of the Company.

Mr. DYETT thought that two Directors was a very small number.

The CHAIRMAN: I should have mentioned that point. We have not filled up Mr. Roberts's place yet. We are looking round, and when we can find someone who can help us materially, and be of benefit to the Company, we shall ask that gentleman to join the Board, but do not press us in regard to this matter now. He then put the motion, and it was carried unanimously.

Mr. WALTERS, in returning thanks, said he might take the opportunity of expressing his own strong confidence in the future of the Company. Owing to misfortunes, not of their own making, they had been in cold water, but with patience he believed that there was a very good future for them. They must, however, have patience. Even now the time was not altogether favourable for them, because, as they were aware, trade was bad all over the world, and telegraph companies must consequently suffer more or less. Things had been very bad on the West Coast of South America, but they must look forward to an improvement there, and then he believed there was a very good future for the Company. The Chairman retired at this meeting, and he had pleasure in proposing his re-election, which he felt sure they would all agree to.

Mr. PACE seconded the motion, observing that Mr. Pender's experience in the telegraph world was certain to be of great value to the Company.

The motion was carried unanimously.

The CHAIRMAN briefly acknowledged his re-election.

Mr. JOHN FRANCIS CLARKE was then elected auditor for the present year.

Mr. LAMONT afterwards proposed a vote of thanks to the Chairman and his colleague for their conduct of the Company's affairs in the past year. He hoped that at the next meeting the Directors would be able to present a satisfactory statement of accounts. There was no doubt that the Directors had had to pass through a very anxious time; but he hoped they were now getting into smooth water, and that the shareholders' patience would be rewarded.

The resolution was carried by acclamation.

The CHAIRMAN: I hope the worst is over now, and that we may look forward to a prosperous future.

The meeting then separated.

Consolidated Telephone Construction and Maintenance Company (Limited).

The thirteenth annual ordinary general meeting of this Company was held yesterday, at Winchester House, Old Broad-street, Mr. C. L. W. Fitz-Gerald presiding.

The SECRETARY (Mr. Charles Curtoys) read the notice convening the meeting, the report of the Directors, and statement of the accounts being taken as read.

The CHAIRMAN said that it would be in the recollection of the shareholders that in the early part of last year they passed special resolutions for the reduction of capital, which, if they referred to the balance-sheet, they would see had been reduced in the following way:—First, they paid back to the Preference shareholders the sum of £27,637, and to the Ordinary shareholders 2s. a share, which amounted to £22,485. In addition to that they wrote off the Ordinary share capital the sum of £22,485. Of this amount £17,485 was written off goodwill, patent rights, &c., and £5,000 from the securities in the balance-sheet of the Edison Gower-Bell Company, which were valued at £16,000, and now stood at £11,000. The result was that their capital now was represented by 24,850 Ordinary shares of 10s. each. There were one or two items in

Digitized by Google

the balance-sheet to which he would like to call attention. The first of these was one which he thought that the shareholders ought to be very much gratified with, and that was the fact that an independent valuation of the plant and machinery having been made, the Directors found that instead of being valued at £5,300, the figure at which they stood in the books, they were worth no less than £7,000. This circumstance showed that the Directors of the Company had been looking very well after the factory, and consequently they thought, with so much in hand, that it was needless to write off anything this year from this item. Their stock of instruments last year amounted to £8,200, and this year it was £7,422—a favourable circumstance, because stock was apt to deteriorate, and the less of it they had in hand the better. The item debtors amounted last year to £8,200, whereas it was now £7,481. Of that sum £5,197 was due by their subsidiary companies. He might mention that the Edison Gower-Bell Company derived all the revenue it received from the Anglo-Portuguese Telephone Company whose position was very satisfactory, and but for the fact that the bringing of money from Portugal here involved such a loss by exchange, they would have received last year double their dividend on the Edison Gower-Bell Preference Shares. This question of exchanges was a comparatively new one, and he hoped the difficulty might by and by be overcome in the interests of all concerned. Their securities were all put down at cost price, and these again were necessarily affected by the difference of exchange. If the exchange were at par, for instance, the United River Plate Company would be paying 13 per cent. As it was that Company was able to pay only its debenture interest. He was very pleased to say that the manufacturing business of the Company had been decidedly improving within the last few months. He did not know whether trade generally was improving or not, but certainly they had no reason to grumble, and he hoped that the improvement would continue to grow. The manufacturing profit this year amounted to £3,070, while last year it was only £1,848. This he looked upon as a satisfactory feature of their accounts. Moreover they had only received £1,830 of the interest from their investments as against £5,799 at the same time last year, and yet they were enabled to pay them the same dividend as was paid then. They had reduced the expenditure from £2,860 to £2,400, which, of course, helped the net revenue. He concluded by moving —

"*That the annual statement of accounts and balance-sheet, with the report of the Directors and auditors as now submitted to the meeting, be received and adopted, and that a dividend at the rate of £2 per cent. per annum be paid, less income-tax, for the year ending March 31, 1894, as therein recommended.*"

Sir ALEXANDER ARMSTRONG, K.C.B., seconded the motion.

The CHAIRMAN in reply to shareholders, said that he had no objection to see the item, general expenses of management £1,890, given in a more detailed form. The fees of the Directors amounted to £1,500, but for three years they had taken only the half of that amount. The question of how to make a larger profit always engaged the attention of the Board; but it was very difficult to see how it could be done. At the same time he saw no object to be gained in winding up the Company. They did pay once 6 per cent., but owing to competition they could afford to pay now only 2 per cent., whether they would ever get up to the higher figure again he could not say, but in the way of manufacturing they had done better this year by something like £1,200.

The resolution was then carried unanimously.

On the motion of the Chairman, seconded by Mr. Henry Grewing, the retiring Directors, Sir A. Armstrong, and Mr. A. H. Baker, were re-elected.

The auditor, Mr. J. G. Griffiths, was also re-appointed, and a vote of thanks having been passed to the Chairman and Directors, the proceedings ended.

The following is the Directors' report:—

In the present accounts due effect has been given to the special resolution of the shareholders passed and confirmed in March, 1893, reducing the capital; £17,485 has been written off goodwill, patents, &c., and £5,000 from the shares in the Edison Gower-Bell Telephone Company. The Preference shares issued to that date have been expunged by their repayment in full; 2s. per Ordinary share has been returned to the shareholders in cash, and 2s. per Ordinary share has been written off in accordance with that resolution.

The operations for the past year show a manufacturing profit of £3,070. 10s., and a net profit of £2,577. 15s. 5d. With the amount carried forward from the year 1892-3, viz., £1,117. 18s. 6d., a balance of £3,695. 13s. 11d. is left for disposal, after making provision for doubtful debts. The Directors propose to pay a dividend of £2 per cent. for the year; to write off a further £63. 16s. 8d. from the cost of the new building, 10 per cent. from furniture account, and £15 from goodwill, patent rights, &c.; to reserve £122. 7s. 11d. for rentals paid in advance; leaving a balance of £1,301. 4s. 6d. to carry forward.

No depreciation of plant and machinery is made in the present accounts. An independent valuation was made on March 21, 1894, by an expert, and his report (which is open to inspection) places the value at an amount considerably in excess of that shown in the balance-sheet. The Directors cannot but think that the shareholders will consider this a valuable testimony to the care taken of their property. This year's accounts exhaust the original expenses incurred in the formation of the agencies.

Business in the latter part of the year became more brisk and profitable; the agencies have been fairly busy, and whilst the Directors see with regret that some large users of the telephone in this country are placing their orders with agents of foreign manufacturers, they trust that ultimately the superior workmanship of the Company's productions will, with fair prices, obtain still more favourable consideration. Every economy that can with prudence be practised is having attention. Friendly relations exist with the various Government and Colonial Departments, and the Directors are using every legitimate endeavour to maintain and increase such. The Directors have again unanimously resolved to relinquish one-half of their fees for the year.

The subsidiary Company, the Anglo-Portuguese Telephone Company, makes progress with its number of subscribers and rentals value. The following table shows the comparison with last year:—

Year ending March 31, 1894.

Subscribers.		Rental.		Increase.	
1893.	1894.	1893.	1894.	Subscribers.	Rental.
2,249	2,320	£14,487	£15,076	71	£589

Gulcher (New) Electric Light and Power Company (Limited).

The following is the long-delayed report of the Directors of this Company. The report is for the period ended June 30, 1893:—

"The accounts from our New Zealand branch, which reached England in November, were insufficient, and had to be returned to New Zealand for completion and correction, involving a delay of nearly five months. Hence the impossibility of calling the present general meeting earlier. Notwithstanding the large order from the New Zealand Electrical Syndicate (Limited), and the hopes thereby raised, the result of the year's working has been a serious loss. The sales in England dwindled down to less than £5,000, and the hire of installations practically ceased. Under the circumstances the Directors have for some time past taken steps to limit the engagements of the Company in view of its possible voluntary liquidation, a course which they will recommend the shareholders to adopt at the ensuing general meeting."

[The balance-sheet which accompanies the above report is a remarkable example of how a trading Company should not be conducted. There is a net loss since the last report of no less than £15,822. 12s. 3d., and there is a strange mixing up of the New Zealand business with that of the business carried on in this country. The stock in England is valued by the Directors at £12,510, off which, by a valuation of the late manager, no less than £4,510 is written. This may be accounted for by the fact that reconstruction is contemplated. The Company appear to have borrowed sums of money at extravagant interest, whereas there is a liability of 5s. per share on 37,723 Ten per Cent. Preferred Shares, which would have realised between £9,000 and £10,000, or even allowing for the calls paid in advance, which represent £3,838, would still have realised nearly the whole of the amount borrowed on mortgage debentures at 6 and 10 per cent interest. Sundry creditors represent no less than £9,794, against sundry debtors £1,740. The only asset of any magnitude possessed by the Company consists of shares in the New Zealand Electrical Syndicate (Limited), regarding which it is not unlikely the shareholders at the meeting at Winchester House, E.C., on Monday next at 11:30 a.m., will require some information. These shares have not earned a penny for the last two years, and the New Zealand branch have, apparently, been allowed to increase their debit by between £4,000 and £5,000. The auditors of the Company, Messrs. Kemp, Ford and Co., certify the balance-sheet "subject to the correctness of the New Zealand account," the valuation of the stock, and to *our report of this day's date*.

A correspondent urges the shareholders to attend the meeting on Monday, and to demand from the Directors a full and particular explanation of the balance-sheet, and certainly the Directors have only themselves to blame if the dissatisfaction now manifested by the shareholders results in some energetic attempt to bring about a more satisfactory state of affairs. The shareholders should insist upon the production of the auditors' report.]

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

ALEXANDER SHANKS AND SONS (LIMITED).—This Company has been registered in Edinburgh, with a capital of £50,000 in £10 shares, to take over the well-known business of engineers, founders and boiler makers carried on under the title of Alexander Shanks and Sons, at Arbroath.

BINNS GAS AND OIL ENGINE COMPANY (LIMITED).—This Company was registered on May 28th, with a capital of £2,000 in £1 shares, to acquire the business carried on at Halifax, of ironfounders, gas, mechanical and electrical engineers, makers of steam, gas, oil, and other engines and machinery, boiler makers, millwrights, machinists, brassfounders, and metal workers. The first Directors are:—Joseph P. Binns, of Luddenden, Yorks.; Henry G. Binns, of Halifax; Frederic W. Thompson, of Luddenden; and Alfred Yates, of Luddenden.

COWPER COLES GALVANISING SYNDICATE (LIMITED).—This Company was registered on May 25th, with a capital of £2,000, divided into 500 "A" and 1,500 "B" shares of £1 each, to acquire all or any of the patent rights referred to in an agreement made between Sir Baldwin W. Walker, Bart., and L. W. North Hickley, and the Syndicate, and to carry on the business of electrical engineers, electricians, engineers, and contractors, electro-metallurgists, galvanisers, manufacturing chemists, manufacturers of electrical and other apparatus for producing, storing, regulating, and supplying electrical energy, galvanism, or magnetism for any purpose. The first Directors are:—Sir Baldwin W. Walker, Bart., 1, Queen's-place, Southsea; L. W. North Hickley, 10, King's Bench Walk, Temple, London, E.C.; Henry Edmunds, 39, Victoria-street, London, S.W., and Emile Garcke, 21, Priory-road, Bedford-park, London, W.

Digitized by Google

ELIESON ELECTRICAL SWITCH (LIMITED).—This Company was registered on May 25th with a capital of £5,000, in £1 shares, to adopt an agreement for the acquisition of the patent rights in Great Britain and Ireland and the English colonies of certain inventions by Mr. C. P. Elieson in relation to electrical switches or circuit breakers, to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, accumulation, and employment of electricity, and to carry on the business of an electric light company in all or any of its branches. The subscribers, with one share each, are:—Lord Galloway, 17, Upper Grosvenor-street, London, W.; Paolo Polenghi, Larchwood, Horley, Surrey; C. P. Elieson, 75, Edith-road, West Kensington, W.; Thomas Smith, Broad-street-avenue, E.C.; Maximilian Friedman, 8, Regent-street, W.; M. Walton-Thomas, Princes House, Palace-street, Westminster, S.W.; Eugene Pellas, 8, Regent-street, W.; and Loftus T. Long, 17, Porchester-square, Hyde Park, W. The first Directors are:—The Earl of Galloway (Chairman), Paolo Polenghi, and Chaimsonovitz P. Elieson.

ROBINSON AND AUDEN (LIMITED).—This Company was registered on May 23rd, with a capital of £35,000, in £10 shares, to acquire the business of agricultural and mechanical engineers, ironfounders, &c., carried on at the Vale of White Horse Iron Works, Wantage, Berks., and to carry on the business of agricultural, mechanical, hydraulic, electrical, gas, metallurgical, chemical, and general engineers, dealers in and suppliers of electrical, engineering, and other goods and apparatus connected with the production of light, heat, sound, and motive power, suppliers of electricity, contractors for the construction of electrical apparatus, and the laying of cables, wires, &c., and to carry on the business of an electric lighting company in all or any of its branches. The first Directors are:—Arthur S. F. Robinson, Arthur C. Auden, and Charles Price.

E. WALLACE AND COMPANY (LIMITED).—This Company was registered on May 24th with a capital of £1,000 in £1 shares, to act as agents for manufacturers or producers of all classes of goods, and in particular of chemical, mechanical, and electrical goods and appliances, and for firms dealing in or making goods appertaining to mechanical and electrical uses, and to carry on as principals or agents the manufacture and sale of mechanical, electrical, surgical, and scientific instruments or appliances; contractors for the sale, letting on hire, erection, and maintenance of mechanical and electrical engineering and other goods and apparatus connected with the production of light, heat, sound, and power, or any other effects by electricity, galvanism, or magnetism, mechanical, electrical, metallurgical and chemical engineers, and electrical engineers, and manufacturers of and dealers in telegraphic and telephonic apparatus and appliances of all kinds in all its branches. The Company was registered without the filing of special Articles of Association, so that no particulars of the management of the concern are available. The following subscribers are connected with the trade:—M. Smith and W. H. Berry.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 16th, is filed, and shows that the whole nominal capital of £1,300,000, in £10 shares, has been taken up, the full amount called, and all calls paid.

ELECTRIC TRUST (LIMITED).—The annual return of this Company, made up to July 15, 1893, was not filed till May 3, 1894. The nominal capital is £60,200, divided into 6,000 shares of £10 each, and 200 Founders' shares of £1 each. 1,675 £10 and 167 £1 shares were taken up and the full amount called, resulting in the payment of £16,917. A letter from the secretary states that the delay in filing the return is owing to the fact that no meeting has been held in consequence of the death of the Chairman, Mr. Spencer Chadwick. No time will now be lost in winding up the Company.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 2nd, has been filed, and shows that the whole nominal capital of £2,500,000, in shares of £10 each, has been taken up, and the full amount called and paid.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—The annual return of this Company, made up to April 5th, is filed. Out of a nominal capital of £100,000, divided into 3,000 £7 per Cent. Preference and 7,000 Ordinary shares of £10 each, all the Preference and 6,837 Ordinary have been taken up and the full amount per share called, resulting in the total payment of £98,370.

INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 10th, has been filed. 17,000 shares, out of a capital of £450,000, divided into 18,000 shares of £25 each, were taken up and allotted. Upon each of these shares the full amount has been called and paid.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 15th, has been filed. Out of a nominal capital of £400,000, in £10 shares, 37,548 have been taken up and allotted, and the full amount called.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to May 7th, is filed. The whole nominal capital of £500,000, divided into 49,900 Ordinary and 100 Founders' shares of £10 each has been taken up. Upon 47,868 shares the full amount has been called, while 2,132 shares have been issued as fully paid. The calls paid amount to £478,421. 9s.

PHONOPORE COMPANY (LIMITED).—The annual return of this Company, made up to May 14, 1894, was filed on May 21st. The nominal capital is £150,000, divided into 100,000 Ordinary and 50,000 £5 per cent. cumulative Preference shares, all of £1 each. At the time of compiling the return 90,000 Ordinary and 28,343 Preference shares were taken up, of which 69,025 Ordinary and 10,380 Preference shares were issued as fully paid. Upon the remaining 20,975 Ordinary the full amount has been called, while upon the remaining 17,963 Preference shares a call of 15s. per share has been made, resulting in a total payment of £34,798. 10s., and leaving £4,139. 10s. in arrear. The principal shareholders are:—C. Langdon-Davies, of 45, Redcliffe-square, S.W. (6,300 Ordinary, 1,300 Preference); Joseph W. Goddard, of Station-street, Leicester (5,690 Ordinary, 1,730 Preference); John W. Cooper and Ernest T. Janson, of 32, Abchurch-lane, E.C. (6,500 Ordinary); and John Abbott, of Silverdale-road, Eastbourne, and Henry D. Kimber, of 79, Lombard-street, E.C. (6,075 Ordinary and 350 Preference).

SOUTH AFRICAN LIGHTING ASSOCIATION (LIMITED).—The annual return of this Company, made up to May 15th, has been filed. 4,050 shares out of a capital of £50,000, in £10 shares, have been taken up, of which 105 were issued as fully paid. Upon 3,000 shares the full amount on 677 shares, £4 per share, and on 373 shares £6 per share has been called.

TELEPHONE COMPANY OF EGYPT (LIMITED).—The annual return of this Company, made up to April 17th, has been filed. Out of a nominal capital of £100,000, divided into 16,000 Preferred and 4,000 Deferred shares of £5 each, 12,071 Preferred and 4,000 Deferred have been taken up; and all of these, with the exception of 71 of the former class, have been issued as fully paid.

CITY NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The transfer books of this Company will be closed from June 15th to 21st inclusive, preparatory to the payment of an interim dividend of 3s. per share (equal to 6 per cent. per annum), free of income tax, for the quarter ended March 31st. The dividend is payable on June 22nd.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended May 27th were £931, as against £844 in the corresponding period of 1893, being an increase of £87. The total receipts for the half-year amount to £19,143, as against £18,579 for the corresponding period of 1893, an increase of £564.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—Notice is given that a drawing of the Six per Cent. Second Mortgage Debentures of this Company will take place at the offices of the Electric and General Investment Company (Limited), 1 and 2, Great Winchester-street, E.C., on Friday, the 8th inst., at 3 o'clock. The debentures are to be paid off on July 1st.

ELECTRIC RAILWAY SHARES.—In common with many other electrical securities the Debenture stock and Preference shares of the City and South London Railway Company have had an upward tendency, and are now quoted:—Debentures 117-119, Preference 12, Ordinary 33-35. Traffics are showing a regular and satisfactory increase.

THE ELMORE COMPANIES.—An upward tendency has recently been shown on the London market in Elmore shares, and the *Financial News*, in calling attention to this fact in its issue of May 25th, dealt with the position of the Elmore Companies generally, and made some special references to the Wire Company, eliciting the following letter from the Secretary:—"Referring to your article to-day, the Elmore Wire Company is not suspended pending the raising of more capital. That was our position some months ago, but since then we have allotted over £30,000 of Preference shares, and, in addition, our bankers will always finance our copper requirements up to £25,000, which, together, gives us a very substantial working capital at our disposal to-day. Our splendid freehold works and plant, capable of turning out 50 tons a week of unequalled product, were long since paid for to the last penny. The Board has been reconstituted, and the name of our new Chairman—Mr. Edward Reynolds, of Sheffield, who is by far the largest shareholder—is a practical guarantee of success. Our sales agents assure us they can readily dispose of four to five times the present possible output at most remunerative prices, and it is now only a question of days before every tank will be fully at work earning a handsome dividend from the first day they start. All our difficulties have vanished. We are to-day closing the London office and concentrating at the works. The present rise is most certainly not a rig, but is, to my knowledge, chiefly due to buying by the customers of the Copper Company, and by the shareholders eager to recoup previous losses."

THOMAS PARKER (LIMITED).—The following advertisement appeared in the *Standard* of Friday last:—

"Thomas Parker (Limited).—The Electric Construction Company (Limited) hold no general or any licence whatever to use the Eickemeyer Patents, or any of them. The only persons entitled to use such Patents (so far as winding is concerned) are the Eickemeyer Company, who have agreed to assign same to Thomas Parker.—A. MacDonald Blair, 5, St. James'-square, Manchester, Solicitor for the Eickemeyer Company, and Mr. Giles Atherton, their Attorney."

This was followed on Monday by an advertisement from the E. C. Company as under:—

"Re Thomas Parker (Limited).—My Board have taken note of the letter from Mr. A. MacDonald Blair and Mr. Giles Atherton, which appears in your paper on the subject of the Eickemeyer patents. I am instructed by my Board to say that they have directed Messrs. Linklater and Co. to issue a writ against Mr. Thomas Parker and Thomas Parker (Limited) to establish our rights.—By order of the Board, the Electric Construction Company (Limited), James Gray, Secretary."

Representatives of Thomas Parker (Limited), including Mr. Parker himself, called at the *Pall Mall Gazette* offices on Friday last with documentary evidence as to the position of affairs. "The documents," remarks the *Pall*

Digitized by Google

Mall Gazette, "seemed to show that there were negotiations between the Electric Construction Company and Mr. Parker for the granting by the latter to the former of a licence to use the patents, but that eventually these negotiations were broken off by Mr. Parker."

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended May 25th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,287.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 838.—Vol. XXXIII. FRIDAY, JUNE 8, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The practical man will, we suppose, seize upon Hertzian waves ere long, patent their application to the use and convenience of man, start syndicates, float companies, and so on. Prof. Lodge showed that a bad contact, a metallic microphone in fact, is so delicately constituted that it will respond to feeble electrical oscillations, propagated from relatively enormous distances from the place where it is stationed. By connecting such an arrangement in circuit with a battery and a sensitive galvanometer, indication of the existence of these waves is instantaneously given. This is surely the essence of the ideal lightning guard—the guard which will give warning long before the storm is near enough to do any damage to the line. A number of these sensitive resistances placed at intervals along the route of any electrical conductor, whether for high pressure power transmission or for telephonic purposes, and connected to indicators at the stations at the ends of the line, would give ample warning of the proximity of a dangerous thunderstorm, and would enable the engineers or operators to make all disconnections requisite to ensure the safety of the plant.

In a letter which will be found in the present issue, Mr. R. M. Deeley refers to the subject of electric waves, and asks on what authority it is asserted that a field of varying electric force must give rise to magnetic forces and *vice versâ.* A direct experimental proof of such an assertion has not yet been actually given, but the truth of it is deducible from universally-admitted laws of electricity. All the laws of electricity can ultimately be reduced to two, which Mr. Oliver Heaviside alludes to as the circuital laws. We need only here refer to one. Any wire forming a closed circuit, if enclosing lines of force, has an electromotive force generated in it equal to the rate of decrease of the lines of force enclosed by the circuit. This electromotive force exists, whatever the nature or resistance of the wire. In fact it exists whether the wire is there or not. It has nothing to do with the wire, any more than the electromotive force of a battery has to do with a circuit in which it may be placed. If the circuit is closed, the electromotive force will produce a current in accordance with Ohm's law. If the circuit is not closed, all that the electric force can do is to cause electric displacement in the ether; but in any case the electric forces are present so long as the magnetic field is varying. A varying magnetic field must, therefore, give rise to electric disturbances in the ether, and the converse of this statement can as easily be shown to be true.

Reference is made by our American correspondent, this week, to the adoption of two new names for electromagnetic quantities. These names are "inductance" and "reactance." They were originated by Mr. Oliver Heaviside, and have been adopted with the meanings given to them by their originator. Although we have frequently expressed our disapproval of the multiplication of names of physical quantities, we are inclined to think that considerable value attaches to this decision of the American Institute. There has always been a shadow of doubt about the meaning of the term "inductance," some writers using it to express the coefficient of induction, and others implying by it a quantity of which the coefficient of induction and the current frequency are joint functions. The ambiguity has probably been due to the absence of any name for this latter quantity; but, now that the term "reactance" has been adopted for it in America, there ought to be no longer any doubt about the meaning of "inductance." The term "reactance" is a distinctly good one, conveying, as it does, by contrast with "resistance" the idea of an elastic reaction as opposed to an inelastic or power-dissipating reaction. These two form the two components of the "impedance," or, as some would call it, the apparent resistance of the circuit through which any periodic current may be passing.

Anent the discussion which has recently arisen in various American electrical periodicals, in regard to the possible use of the earth as a means of transmitting intelligence without wires, we may observe that there is no inherent difficulty on account of the fact that an immense number of messages would be required to be transmitted in all directions simultaneously. It is conceivable that either or both of two physical operations might be employed to sift out these simultaneous messages: the operation of conjugate foci, and the operation of resonance. Something quite as complicated as the use of the earth for this purpose goes on in each tiny portion of the surface of a piece of looking glass. Just think of the infinite number of images which are being reflected in an infinite number of directions from every element of the reflecting area, and it will be confessed that the kinetic condition of the ether at this surface is inconceivably complicated. Yet there is no confusion between the various images on account of the complexity of action of the delicate machine

Digitized by Google

which propagates them. Just in the same way, there is not necessarily any confusion between an infinite variety of pulsating electromagnetic messages propagated through the earth. But, between the denial of the inherent impossibility and the assertion of the practical possibility, there is a great gulf fixed. Who shall bridge it?

THE ordinary railway engineer may be a little puzzled at the anxiety with which electric railway engineers in America are seeking to obtain continuously welded rail tracks. There are so many practical difficulties in the way of dispensing with the expansion gap, and the cost of continuous welding is relatively so high, that it is not at first sight evident why such strenuous efforts should be made on behalf of welded rails. The secret lies in the pressing necessity which electric railway engineers are under, to provide an efficient rail-return for the current. All sorts of rail bonds have been tried and found wanting, and the only hope lies in an actual metallic union between rail and rail. We describe this week a method of track welding which has been adopted on one of the American lines, and which appears to give a very efficient connection at the rail joints. The method is interesting from the fact that the welding current is not passed through the butt joint from rail to rail, but is sent transversely to the rails between two pairs of clamping lugs of mild steel placed on either side of the butt joint. The actual union with the rails is produced by mechanically squeezing the pasty steel into the fissure between the rails, at the same time the welding metal being case-hardened by a supply of carbon. Enough plastic metal is forced into the gap on either side to make a butt weld in the middle, so that the joint practically consists of an upper and a lower H-piece electrically welded at every point of contact with either rail. The mechanical advantage of this method of electric welding would appear to consist chiefly in the fact that the work of forcing the rails into a true butt contact is not put upon the welding machine, as would be the case if the welding current had to pass from rail to rail; and, thus the uncertainty of a weld over the entire section is removed.

THE orthodox objection to raise against continuous rails, 500ft. or more in length, is the variation of length due to change of temperature. It represents a very serious, but happily, not insuperable difficulty. A metal rail varied between mid-winter midnight temperature and that of an August noon will usually alter considerably in length. But it does not necessarily do so; for it is possible to constrain the rail so that it shall remain at practically constant length. This alternative sets up a stress in the rail and weakens it; it probably also hastens that interesting, but very disastrous, process of deterioration which has been so ably investigated by WÖHLER and others. Moreover, since the rail and the things which hold it in place are not perfectly elastic, there may be set up a gradual process of "creeping," whereby the relative position of the rails may be found at the end of some weeks to have appreciably changed. It is not likely that any serious "hogging" or buckling will take place if the rails are properly secured; but, until there is more certain experience of these things, very careful inspection ought to be made to discover whether any slow-period changes are liable to occur on account of imperfect elasticity.

THANKS to the unwearying vigilance of the County Council, a grave danger which threatened the welfare of the inhabitants of this City has been warded off. On Tuesday last a gang of miscreants were discovered trying to run a steel tube through the London clay. Captured, and put to the question (in Committee Room No. 5), the prisoners alleged that they were merely poor out-of-work company promoters hoping to construct an electric railway from the City to Epping Forest, and thereby relieve the existing lines of some of their superabundant traffic, and secure a minimum of 3½ per cent. for the thrifty investor. The culprits were at once sternly warned that the sovereign people could not be trifled with in this manner, and that their offence could only be purged by at once promising as a votive offering to carry all county councillors and their supporters nine miles for one penny for all time. This magnanimous proposal not being to the liking of the promoters, they were summarily ejected, *i.e.*, their Bill was thrown out.

THE project being, however, of some public utility, we may perhaps be allowed to suggest that the job should be carried out either by the County Council's own staff or by the unemployed, a short Act of Parliament being passed conferring the necessary knowledge upon all concerned. As it is also desirable that the money should not be provided by those in any way likely to be benefited, another short Act might be passed empowering the Council to levy some sort of poll-tax, say one penny on every silk hat entering the City area between the hours of nine and eleven forenoon. Meanwhile, London waits for its electric railways and English capital flows to other lands.

Telephonic Communication in Germany.—It is proposed to establish telephonic communication between Berlin, Tilsit and Memel.

Manchester Ship Canal.—Preparations are now being carried out for lighting the locks at Barton, on the Manchester Ship Canal, by arc lights.

Derby Electrical Exhibition.—This exhibition has been so successful that arrangements are being made for continuing it for another week.

Electricity Supply in Germany.—The authorities of the electric lighting station at Altona have just reduced the price of electrical energy for motor purposes to 2½ pfennigs per hectowatt hour (2½d. per kilowatt hour).

Destruction of an American Power Station.—A boiler explosion occurred at the Southern Electric Light Company's power station at Philadelphia. A loud roar was heard throughout the city, and every light on the circuit was extinguished.

New Books.—Messrs. Longmans, Green and Co. have brought out, in book form, Prof. Unwin's "Howard Lectures" "On the Development and Transmission of Power from Central Stations," which were delivered before the Society of Arts last year.

Royal Society.—At yesterday's meeting the election of Fellows took place, and the following papers were read: Prof. C. V. Boys, "On the Newtonian Constant of Gravitation;" Mr. S. Bidwell, "On the Recurrent Images attending Visual Impressions."

The Electric Lighting of the Embankment.—At the last meeting of the London County Council the Highways Com-

Digitized by Google

mittee recommended that the generating station for lighting the Embankment and the Waterloo and Westminster Bridges be constructed by the Works Committee. This was agreed to.

Electrical Trade Section.—At a meeting of the Electrical Trade Section yesterday, Mr Emile Garcke was elected chairman, and Mr. Alexander Siemens, deputy-chairman: Major Flood Page resigning the chairmanship after two years' tenure.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Lagos-Accra	May 21, 1894	June 6, 1894.
Bissao-Bolama	Nov. 24, 1893	—
Brest-St. Pierre (P.Q. Co.)	Mar. 29, 1894	—
Accra-Kotonou	Apr. 1, "	—

A New Telegraph Code.—A "Weather and Famine" Code has been prepared by Mr. Tucker, Registrar in the Indian Revenue and Agricultural Department, for use between the Government of India and the Secretary of State. The code words are French.

London County Council (General Powers) Bill.—This Bill, which has passed the House of Commons, came on Tuesday before the examiner of standing order proofs in the House of Lords, and was reported to have failed to comply with the standing orders in respect to one clause which was not covered by the notices.

The Electric Lighting of the French Chamber of Deputies. The Palais Bourbon, it is announced, will shortly be lighted by electricity. The firm of Brégeut is ready to do the job for £20,000, and to run and maintain the plant for £2,880 per annum for a period of ten years, against £4,800, the annual amount of the lighting bill at present.

More Fanciful Candle-Powers.—The search light, constructed in France, which was exhibited at the Chicago World's Fair, has been erected at Sandy Hook, and was lighted for the first time on Monday night. The intensity of its light is stated to be 194,000,000 candle-power. How much higher, we wonder, will the rating of search lights be carried?

Prize Essays.—It is announced that the Smith prizes this year have been awarded to Sydney Samuel Hough, B.A, scholar of St. John's, for an essay "On the Oscillations of an Ellipsoidal Shell containing Fluid," and to Henry Cabourn Pocklington, B.A., scholar of St. John's, for an essay "On the Steady Motion and Small Oscillations of an Electrified Hollow Vortex."

Leaflet Instruction in Electrical Engineering.—The *Electrical Engineer* of New York will shortly begin the publication, under the title *Electrical Engineering Leaflets*, of a book written by Prof. Houston and Mr. A. E. Kennelly. The Leaflets will be issued weekly, in three grades—Elementary, Intermediate and Advanced—each grade consisting of 35 weekly parts, all three to issue simultaneously.

Resonating Conductors.—The *Electrical Engineer* of New York, in a leading article stating that Prof. Pupin "has devoted himself specially to the study of 'resonance' effects at low frequencies such as those directly obtainable from alternators or other electric current generating devices," further understands that "Dr. Pupin has carried his experiments involving the same principles into the realms of electric lighting by means of vacuum tubes, and that most promising results have already been obtained as to light without heat."

Telegraph Blunders.—A few weeks a ago a cablegram from London announced that the Government had annexed the Tuesday Islands, and the good folks at the Cape were set wondering, not only at the boldness of the Ministry, but at the unaccountable parsimony of the gazetteers in affording no clue to the position of those coveted possessions. When the mail arrived with the English papers it was discovered that the Government had really annexed no more than the Tuesdays which had been given up to private business in the House of Commons.

Obituary.—We regret to record the death, on the 30th ult., at Park House, Budleigh Salterton, of Vice-Admiral George William Preedy (retired), C.B., aged 77. Admiral Preedy was in command of H.M.S. "Agamemnon" during the laying of the first Atlantic cable in 1857.——We regret to also have to record the death of Mr. Thomas Eccleston Gibb, which occurred on Wednesday at his residence in Lady Margaret-road, Kentish Town. It was largely owing to his initiative that the parish of St. Pancras adopted the electric light. Mr. Gibb was an Associate of King's College and a Fellow of the Statistical Society.

A Telephone Circuit Protector.—Amongst the novel devices at the Southern Bell Telephone and Telegraph Company's new exchange in Atlanta (Ga.) is the Wotton protective device against heavy currents. This circuit-breaker consists simply of a small graphite cylinder capped at both ends with brass caps, to which the circuit wires are connected. A small amount of fulminate of mercury is placed in the ends of the graphite cylinder under the caps. On the passing of an excessive current a small explosion occurs, blowing out the graphite and disrupting the circuit.

London Electric Railways.—The Bill promoted by the Central London Railway Company will pass unopposed through the House of Lords, no petitions having been lodged against it within the time allowed by the Standing Orders. By this Bill, which has already been sanctioned by the House of Commons, an extension of time is granted until 1900 for constructing this railway. The Charing Cross, Euston and Hampstead Railway Bill, which gives power to that company to acquire additional lands, will also pass as an unopposed Bill through the Second House.

The City Engineer.—At the meeting of the City Commission of Sewers on Tuesday the Special Committee brought up a report on the reference to inquire, owing to the death of Colonel Haywood, into the duties and emoluments of the engineer's department. They recommended that Mr. Ross, who since 1882 had been chief assistant to the late engineer, and 22 years in the department, should be appointed chief of the engineer's office, with power to call in consulting advice under the authority of the Court when deemed expedient, and that his salary, now £650, be increased to £900.

Research Fellowships.—The Registrar of Owens College, Manchester, announces that at least two Bishop Berkeley Fellowships of the value of £100 per annum, to date from September 29th next, are offered for award. Evidence must be presented of ability to prosecute some special study or research in one among several of the chief subjects of the college curriculum in arts, science, and medicine. A limited number of appointments will be made on the same date to Honorary Research Fellowships. Applications should be sent on or before June 22nd to the Registrar.

Oil Fuel.—We have received from Mr. Henwood a letter about the marine boiler which he described at a recent meeting of the Institution of Electrical Engineers. He reiterates his claims, and makes a number of general assertions, summing up by stating that:—"This boiler is the very best type that has ever been devised for burning oil fuel, . . . and the life or endurance will probably be about three times as long as the ordinary marine boiler. . . . The weight under steam will be only about one-eighth; the space occupied, the consumption, and the cost of construction per indicated horse-power about half as compared with the ordinary marine boiler in proportion to power." We understand that he does not wish illustrations to be published at present.

The May Island Light in a Fog.—Another instance of the failure of an electric light to pierce a fog is given by the wreck of the Dundee steamship "Jasper" upon the May Island on the night of April 16th. The vessel was carried out of her course by currents; and with only a couple of minutes' notice, the island was struck 500 yards from the lighthouse. It is a powerful electric light, erected about eight years ago, at a cost of £60,000, and in clear weather it is visible for a distance of 20 miles. A fisherman who gave evidence at a Board of Trade inquiry stated that when he was about a mile from the island he could not see the light, although he could see the light on the Fifeshire coast, an oil-light, which was 2½ miles off.

Institution of Civil Engineers Premiums.—Amongst the awards made for original communications submitted during

Digitized by Google

the part session are the following:—Telford Medals and Telford Premiums to J. H. Greathead and Francis Fox for their joint Paper on "The Liverpool Overhead Railway;" a George Stephenson Medal and a Telford Premium to Thomas Parker, for his Paper on "The Electrical Equipment of the Liverpool Overhead Railway;" a Watt Medal and a Telford Premium to Bryan Donkin, for his Paper intituled "Experiments on the Condensation of Steam in Cylinders of Iron and other Metals."

Smoke Consumption.—A competition of smoke-consuming apparatus has been decided upon by the Paris Municipal Council, which has set aside a sum of £320 for the purpose. An elaborate programme of conditions is to be drawn up, and the apparatus submitted for competition, which must be practical and not costly, will be subjected to exhaustive tests at the municipal waterworks by a commission composed of engineers attached to the Paris Municipality and members of the Hygienic Council, with power to add to their number a scientific man, a member of the Committee of Arts and Manufactures, a manufacturer, and a member of the Municipal Council.

Thunderstorms.—Violent and prolonged thunderstorms, accompanied in some instances by cyclonic storms, have visited various parts of the country during the past week. Horses and cattle have been killed or maimed in a great number of places in the West of England. At Bath a man was severely injured, and the crew of a boat off Lowestoft were rendered unconscious, it is said, by the violence of a shock with which their craft was struck. Lightning has often given fire brigades enough work to do to extinguish fires at buildings it has struck, but at Rugby this week it has varied the usual course of striking the fire alarm and ringing up the brigade, although it did not want them for any conflagration.

Flood Warnings by Telegraph.—The Birhi-Ganga, one of the Himalayan headwaters of the Ganges, runs down a gorge with cliffs rising to 4,000ft. on either side. In September and October last, certain of these cliffs fell down into the gorge and blocked it up with an obstruction two miles long and one mile broad. The lowest height of this natural dam is about 850ft. above the bed of the stream, so that a lake many hundred feet deep is accumulating behind it. Official inspection has shown that there is no danger of the dam giving way as a whole, but the upper 250ft. is of lighter material, and is naturally less thoroughly consolidated than the base, and a sudden giving way of this portion would result in a bad flood. A watch has, therefore, been set upon the obstruction, and a special telegraph line has been run to enable prompt warning to be given to the threatened inhabitants.

London, Walthamstow, and Epping Forest Railway.—On Tuesday it was announced to Sir John Kennaway's Committee on the above Bill that the negotiations with the London County Council with regard to the terms imposed upon the promoters as to workmen's trains had failed, and Mr. Balfour Browne asked the Committee to insert a suspensory clause providing that they should not come into operation until 3½ per cent. had been paid upon the Ordinary shares, stating that without such a clause they would not be able to raise the capital, and must withdraw the Bill. Mr. Pember, for the County Council, asked that if a suspensory clause were introduced it should be for a definite limited time, the term he suggested being three years. The Committee expressed their willingness to insert a suspensory clause for five years, but this did not satisfy the promoters, and the Bill was withdrawn.

Jubilee of the American Telegraph.—The *Electrical Engineer* of New York calls attention to the fact that the present year is the Jubilee of the United States system of telegraphs. In 1843 Congress voted £6,000 for tests of the electric telegraph, and on May 24, 1844, the historic message "What hath God wrought?" was despatched by Miss Annie G. Ellsworth, now Mrs. Roswell Smith, from Washington to Baltimore. In a characteristically interesting little article, our New York contemporary recalls to mind the various episodes of that classic period in the history of land line telegraphy. In a minute dated June 26, 1844, Morse deals with the question of the repair of aerial lines, and makes the—to us—quaint-sounding suggestion that "very little interruption would take place if the train that discovered a break would stop not more than five minutes, and being furnished with pieces of wire already prepared for the purpose, anyone could simply unwrap and scrape the broken ends, and unite them by twisting the ends of the pieces of wire to them; and then give notice of the place to the inspector at either terminus, that a more permanent repair may be made." We commend the suggestion to the passengers by, and officials of the South-Eastern Railway, who have many such opportunities of useful leisure.

Great Northern Telegraph Company.—On Thursday last week the Great Northern Telegraph Company completed the 25th year of its existence. The event was commemorated wherever the Company has stations 18 in all, the London staff being entertained at dinner at Seyd's Hotel. In Copenhagen the King of Denmark sent his congratulations on the event to the Chairman of the Company, and a banquet was held in the evening—on June 1st. At the same time a large company dined at the Savoy Hotel, among those present being the Danish Minister, the Swedish and Norwegian Minister, Sir John Pender, G.C.M.G., M.P., Mr. Lamb, C.M.G., Mr. Benton, the Danish Consul-General, Count Ahlefeldt-Laurvig, and representatives of other telegraph companies. The Danish Minister proposed "The Great Northern Telegraph Company." He believed that the work of the Company would bear comparison with that of any other telegraph administration. Practically, direct cable communication between Great Britain and the North of Europe had not been totally interrupted for a single day during the 25 years of the Company's existence. In China the Company were the pioneers of the telegraphs. They overcame the resistance of the most anti-progressive power on the face of the earth, the superstitions of the Mandarins and people, and the difficulty of adapting the Chinese language to telegraphic correspondence. Mr. Nielsen, the representative in England of the Great Northern Telegraph Company, who presided at the dinner, in responding, spoke of the kindness and assistance which his Company had met at the hands of the Post Office and English cable companies. Mr. Lamb, in replying, referred to the cordial relations which existed between the General Post Office and the Great Northern Company, and paid a hearty tribute to Mr. Nielsen's great ability and integrity. The next toast was "Sir John Pender," which was proposed by the Danish Minister. Sir John Pender, he said, had been connected directly or indirectly with every submarine cable enterprise during the latter half of the century, and his name would appear on almost every page when the history of those enterprises came to be written. Sir John impersonated those resources of genius, enterprise, and perseverance which had secured to Great Britain the place it occupied amongst nations, stimulating other nations to that competition from which all progress sprang. Sir John Pender said in his reply that the evening's celebration carried him back over almost the whole period during which he had been actively connected with submarine telegraphy. He asserted that there had been no more important factor in the progress of civilisation and the extension of commerce than the development of submarine telegraphy, and this he was sure would be borne out by those who would write the history of the present century. The importance and practical value of these connections were admitted by some of the European governments, but he thought the companies should be more fully recognised by the administrations and consulted. It gave him much pleasure to be present on this occasion, and to testify to his admiration of the good work done by the Great Northern Company. They had worked very well together—sometimes with a little friction—but on the whole with a good understanding. He hoped they would continue to work together in harmony and in unity. The Chairman and the Managing Director of the Company have each received valuable presents from the Board of Directors and from the staff. The Directors of the Company, in order to mark their appreciation of their employés' services, have given to each a present equal to from one to six months' salary, according to the length of service. Everyone in the service is included in this mark of appreciation—clerks, messengers, coolies, and housekeepers.

ON HERR LENARD'S EXPERIMENTS ON THE MAGNETIC ACTION OF CATHODE RAYS.

BY GEO. FRAS. FITZGERALD, F.R.S.

In a former communication upon Herr Lenard's experiments (*The Electrician*, Vol. XXXII., p. 573, March 23, 1894) it was pointed out that the experiments so far would be consistent with the supposition that cathode rays were rays of light of a very high frequency, except for the fact that they are deflected by magnetic force, a phenomenon of which we have no other evidence, and which makes it practically impossible at present to suppose that cathode rays are of this nature. It was further pointed out that if this deflection were an action on the emitting surface, and not on the ray, it might be again possible to explain these cathode rays by the supposition that they are rays of light. Herr Lenard's more recent experiments seem entirely at variance with any such supposition, while there is nothing in them that, in the same conclusive way, proves that they are not streams of electrified molecules or atoms.

Years ago Messrs. Spottiswoode and Moulton showed that it was possible to start from one side of a glass plate what they considered to be the same as the cathode part of electric discharges, by a sufficiently sudden charging of the opposite side of the plate. They showed that it was thus possible to produce these rays in air at considerable pressures, and they seemed to consider the phenomenon quite analogous to the production of the electric aura from points. They showed that these discharges could be driven partly along an exhausted tube without reaching the far end, and considered that the discharge went out and returned by the way it came. If this were the case with cathode rays in general, it would account for their not appearing to electrify bodies, though it would also require the assumption that the returning discharge returned in an irregular way, so that its deflection by a magnet was imperceptible. Certainly Herr Lenard's observation that these cathode rays do not electrify a conductor placed in them proves that either the quantity of electricity concerned is very small, or that the charges cannot leave the gas. Either of these suppositions is possible. The phenomena of phosphorescent illumination, heating, and pressure, that have been attributed to projected molecules have been ascribed to their kinetic energy, and not to the electric energy they possess, and there are many experiments that show that a charge cannot leave the gas easily.

It is to be regretted that Herr Lenard does not seem to have observed whether the phosphorescence or the spectrum of the cathode light depends at all on the nature of the gas. If it does it might finally decide whether the molecules can be projected through these thin windows. That there is no increase in pressure in the vacuous tube only shows that the same number go out as come in, and although it is *extremely* improbable that any gas is carried through glass and mica, yet it would be desirable to finally disprove the supposition, especially as there are several experiments by Mr. Daniell, Dr. Shields, and others, showing that electrolytic ions can penetrate considerable thicknesses of metallic plate.

From Herr Lenard's most interesting and important observation, that the deflection of the ray depends on the pressure of the gas in the tube in which the ray is generated originally (he does not seem to have changed its nature), and not on the nature and pressure of the gas in which it is deflected, it follows that, if the rays are paths of projectiles, they must either pass through the window or else be projected from it by some action which behaves like a blow given to it from the other side. The action may, of course, be electrolytic in its nature, or it may be an ordinary blow accompanied by some electric action which accounts for the magnetic action on the projected molecule. Blows delivered to one side of a plate would project molecules from the other side, with different velocities depending on the nature of the blow and on the mass of the molecule, so that a hypothesis of this kind would be quite accordant with Herr Lenard's observation. The fact that the magnetic effect is independent of the mass of the molecule struck is explicable by supposing the electrical charge to be the same for all molecules. Some of these molecules in traversing the gas would collide with others, so that their paths would not be quite straight, and their velocities would be less than that of the unstruck molecules, and so would produce the penumbra Herr Lenard has observed when the vacuum is not perfect, and this penumbra being due to more slowly moving molecules, would be more deflected by the magnetic force than the more quickly moving central core.

There does not seem anything in these observations at all at variance with the supposition that we are dealing with rapidly moving molecules of matter, and until this hypothesis is *disproved* it is hardly safe to venture on new properties for the ether. The way in which the emission theory of light explained refraction, accounts for the ease with which Herr Lenard is able to give an optical turn to these observations. Even though it can be shown by rotating the tube and thereby producing aberration, or by some other method, that the velocity of projection must be comparable with that of light, and consequently improbably great for matter molecules, yet we really know nothing to prove that such velocities are in any way impossible. The velocity of the molecules in a comet's tail, which polarise light and are almost certainly material, is very great indeed, and if only a few molecules are concerned the amount of energy required to produce, even very great velocities, is not very great. A hydrogen molecule moving with the velocity of light has an energy of less than half a millionth of an erg, a very small quantity, and it is evidently possible to regulate the numbers of molecules involved so as to account for whatever energy is required to explain the phenomena.

Even though sufficient reasons were forthcoming for rejecting the theory that these rays are due to projected molecules, there are other possible suggestions such as that they are straight Grotthüs chains of molecules, which bend under magnetic force. This might account for a velocity of propagation of actions along them, comparable with the velocity of light, without requiring the component matter to move with this velocity. In fact, until the matter present has been reduced very much beyond what has been attained, and it has been shown that these phenomena increase instead of diminishing, and that there is no very slow projection of the material of the plates, such as darkens the glass in glow-lamps, it will be very difficult indeed to prove that any of the phenomena hitherto observed, are due to the ether, and not to the matter present, because so far the phenomena are quite like those that would be due to moving electrified matter, and especially the magnetic actions, are quite unlike anything we know of the properties of the ether.

It would certainly be very much more interesting to find in them a new property of the ether. It has, quite possibly, many properties of which we know very little. It is, possibly, the cause of gravity, and of chemical forces, though the former of these is certainly and the latter are probably quite different from electric and magnetic forces. It has been often pointed out that upon almost any vortex atom theory there should be actions which are simultaneous throughout space, which are not propagated in the ordinary sense of the word, but are due to the motion constituting each vortex atom being extended throughout all space. If the ether has structure, which is almost certain, electromagnetic actions are probably due to an average change of structure, and in that case there may be actions due to the changes whose average we observe. Just as the pressure of a gas is due to the average velocity of its molecules, while its rate of diffusion depends on these actual velocities themselves, and on the sizes of the molecules. It would undoubtedly be much more interesting to see in these cathode rays, in auroral streamers, and possibly in the solar corona, and in comets' tails, a new etherial phenomenon rather than an example of the old humdrum electromagnetics of the last twenty years; but notwithstanding Herr Lenard's experiments, and Lemström's auroral streamers reaching the earth, and observations of their extending hundreds, if not thousands, of miles from the surface of the earth, notwithstanding the help it would give us in explaining magnetic storms by cathode rays from the sun, without filling space with an undue amount of matter, nevertheless we must make sure that the known laws of the old humdrum electromagnetics cannot explain the observations before framing additional hypotheses. Science generally advances by reducing the number of, rather than by multiplying hypotheses.

A METHOD FOR THE TREATMENT OF ROTATING OR ALTERNATING VECTORS, WITH AN APPLICATION TO ALTERNATE CURRENT MOTORS.

BY PROF. GALILEO FERRARIS.

(Continued from page 131.)

Part II.—Application to Magnetic Fields and to Electric Motors with Alternate Currents.

13. We can apply the general considerations above explained to the special case in which the vectors treated of are magnetic forces.

In this case the propositions of articles 8, 9, and 10, show at once how, by means of two or more alternating magnetic fields of fixed direction you can produce a rotating magnetic field. Moreover, we show how a rotating magnetic field can be produced by means of two or more alternating currents of different phases. In other words, therein is comprised the fundamental principle of electric motors for alternating polyphase currents.

Vice versâ, the proposition of Article 3 shows how an alternating magnetic field, or a flux of alternating induction can always be considered as resultant of two or of more fields, or of two or more fluxes of constant value rotating some in a right-handed sense and the others in a left-handed sense. Now, this mode of considering a magnetic field or a flux of alternating induction may prove very useful in the study of induced currents in conductors placed in the magnetic field, and in the study of the force which this latter exerts on them. It may, in consequence, prove useful in the study of fundamental phenomena in many kinds of electric apparatus, and especially in electric motors for alternating currents. To give an example of such application we shall here treat of these last.

14. *Synchronous Motors.*—Let us consider first an armature formed of a single coil, of which the spires are in planes perpendicular to a common axis $o\,a$ (Fig. 12), and let us suppose that it

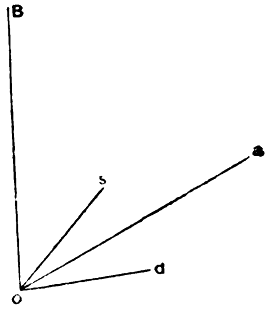

Fig. 12.

can rotate in the plane of the figure round an axis o in a magnetic field where the magnetic induction has the uniform value B and the constant direction o B. If such a coil is traversed by an electric current, it is equivalent to a magnet of axis $o\,a$, the magnetic moment of which is obtained by multiplying the sum of the areas of the turns by the strength of the current in absolute electromagnetic measure. We can represent this magnet, and therefore also the coil traversed by the current by means of a vector having the direction $o\,a$ and a magnitude equal to the aforesaid magnetic moment. If the current is alternating with the frequency n, the vector also is alternating with the same frequency, and we can represent it, according to our method, by $o\,a\,s\,d$. Making use of this representation is equivalent to substituting for the alternating magnet $o\,a$ two rotating magnets, the magnetic moments of which are represented by $o\,d$ and by $o\,s$. Calling the amplitude A, $o\,a$ and d and s the magnitudes of the two rotating vectors $o\,d$, $o\,s$, we have $d=s=\dfrac{A}{2}$.

This being assumed, let us consider the forces exercised on the coil by the magnetic field in which this is situated. The forces are reduced to a couple whose moment is $B\,.\,a \sin B\,o\,a$, and by the theorem set down in Art. 11 is equal to the sum

$$B\,d \sin \delta + B\,s \sin \sigma,$$

where by δ and by σ are represented, as before, the angles which the two rotating vectors left-handed and right-handed d and s make at the given moment with o B. If the coil is at rest, the vectors d and s turn with the same frequency, n, the one in a right-handed sense, the other in a left-handed sense, and by the proposition in Article 12 (4th case), the mean values of the products $B\,d \sin \delta$ and $B\,s \sin \sigma$ are equal to zero. Whence the mean value of the moment of the said couple is equal to zero. If we make the coil rotate round the axis o, with a frequency m, the vector $o\,a$ turns with it, and the two vectors $o\,d$ and $o\,s$ begin to turn with angular velocity equal to the algebraic sum of the velocity which they have relatively to the armature, and of the velocity which they have common to this. If, for example, the armature turns to the right, the rotating vector d turns in space with the frequency $n+m$, and the vector s turns with the frequency $n-m$. Meanwhile, since m is different from n, the mean values of the moments of the couple are again equal to zero. But if $m=n$, the frequency of d becomes equal to $2\,n$, and that of s is reduced to zero. The current of the armature is equivalent then to two magnets of constant magnetic moment, one of which, d, turns in the direction of the armature with a double frequency, and the other, s, remains fixed in space. The fixed direction of this last is that through which there passes the axis, $o\,a$, of the rotating coil at the moment in which the alternating current in it has the maximum strength. Such a direction makes, with o B, a fixed angle, which we shall represent by ς. In this case the moment of the couple acting on the armature has no longer a mean value equal to zero; then, in fact, only the mean moment of the couple acting on $o\,d$ is equal to zero, or the mean value of the product $B\,d \sin \delta$; whilst the moment of the couple acting on $o\,s$ has the constant value

$$B\,s \sin \varsigma,$$

or

$$\frac{1}{2}\,A\,B \sin \varsigma.$$

This couple tends to close the angle $s\,o$ B. If such angle is, as in the figure, to the right of o B, or on the side towards which the armature turns, the couple opposes itself to the movement, causes the expenditure of energy, the apparatus acting as a dynamo. If, instead, the angle B $o\,s$ lies to the left of o B, or on the side opposite to the movement, the couple acts in the direction of the rotation, it does work; the apparatus works as an electric motor; it is, in the simplest form, a synchronous motor.

The motor couple of this motor varies between 0 and $\frac{1}{2}$ A B when ς varies between 0 and $\frac{\pi}{2}$. For values of ς less than $\frac{\pi}{2}$ the action of the motor is stable. If, in fact, the resisting couple is augmented the armature is somewhat retarded, the angle ς increases, and the moment of the motor couple increases with it. If, instead, the resisting couple is diminished, the armature tends for a moment to be accelerated, thus the angle ς diminishes, and the motor couple diminishes with it.

15. *Asynchronous Motors. Closed Armatures placed in a Rotating Magnetic Field.*—Let us consider in the second place an armature formed of N windings, or of N elementary spirals closed on themselves in short circuit, and arranged regularly at equal angular distances in opposite diametral planes, all about an axis of rotation. Let us call S the area, r the resistance and L the coefficient of self-induction of one of the spirals. Let us imagine then that the armature is in a rotating magnetic field, in which the magnetic induction, constant and uniform, has the value B, and turns *relatively to the armature* with a frequency u.

In the elementary spiral the normal of which makes with the induction B, at the end of the time t an angle a, there passes at that moment a flux of induction $B\,S \cos a$; whence by the variation of a due to the rotation of B in respect to the armature, we have in the spiral an electromotive force

$$2\,\pi\,u\,B\,S \sin a.$$

This electromotive force produces in the elementary spiral a current of strength i given by the formula

$$i=\frac{2\,\pi\,u}{\rho}\,B\,S\,\sin\,(a-\phi),$$

where ϕ is the angular value of the retardation of phase of the current in respect to the electromotive force given by the relation

$$\tan\,\phi=\frac{2\,\pi\,u\,L}{r},$$

and ρ is the apparent resistance of the spiral, or

$$\rho=\sqrt{r^2+4\,\pi^2\,u^2\,L^2}.$$

Such a current is equal to a magnetic shell, whose magnetic moment is equal to i S, or to

$$\frac{2\,\pi\,u}{\rho}\,B\,S^2 \sin\,(a-\phi).$$

And can be represented by a vector having the direction of the normal to the plane of the spiral, or, as we may say concisely, the direction a.

Now, if this vector is projected on the straight line which B makes with the angle ϕ, and then on the perpendicular to it, we have, repectively,

$$\frac{2\,\pi\,u}{\rho}\,B\,S^2 \sin\,(a-\phi) \cos\,(a-\phi),$$

and

$$\frac{2\,\pi\,u}{\rho}\,B\,S^2 \sin^2\,(a-\phi)\,;$$

and if we calculate the mean values of these projections for a, comprised between 0 and $2\,\pi$, we find that these mean values are,

Digitized by Google

respectively, zero and $\frac{1}{2}\frac{2\pi u B S^2}{\rho}$. Thence the N spirals are equivalent in the main to a magnet of magnetic moment—

$$A = \frac{N}{2}\frac{2\pi u}{\rho} B S^2,$$

the axis of which makes, with the direction of B, the constant angle $\phi + \frac{\pi}{2}$. Such a magnet follows B in the rotation, being always behind at the angular distance $\phi + \frac{\pi}{2}$. If in Fig. 13 it is supposed that the magnetic field turns *relatively to the armature* in the direction of the arrow u, and if O X is perpendicular to the direction O B of the magnetic induction, the direction of the equivalent magnet to the armature is that of O A, which makes with O X the angle X O A $= \phi$.

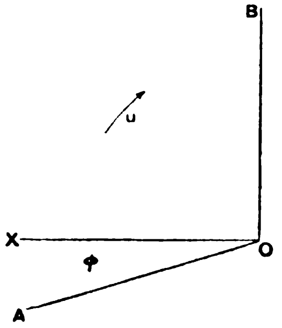

Fig. 13.

16. *Motors with Rotating Field.*—An armature like that which we have just considered, situated in a rotating magnetic field produced by means of a system of polyphase currents, constitutes a motor with rotating field. The motor couple is that which the magnetic field would exert if, in the place of the armature, there were substituted the equivalent magnet previously considered. The moment (or torque) of this is thus (Fig. 13) A B sin A O B, calling it K, and substituting for A the value found in the preceding article, we have

$$K = \frac{N}{2} B^2 S^2 \frac{2\pi u . \cos\phi}{\rho}.$$

Remembering that $\cos\phi = \frac{r}{\rho}$, we can also write

$$K = \frac{N}{2} B^2 S^2 r \frac{2\pi u}{\rho^2},$$

or

$$K = \pi N B^2 S^2 \frac{r u}{r^2 + 4\pi^2 u^2 L^2} \quad . \quad . \quad . \quad . \quad (1)$$

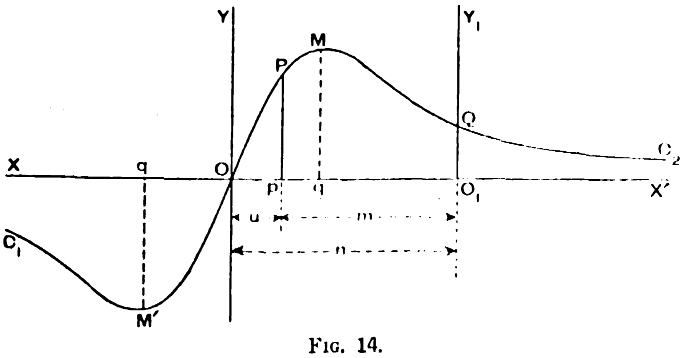

Fig. 14.

In this expression the letter u represents the frequency of the *relative motion* of rotation of the magnetic field with respect to the armature. The formula gives the relation between the couple of rotation K and the frequency u; and it is easy to see what would be the form of the curve with which the formula is translated when we take u as abscissa and K as ordinate.

The (1) can be written

$$K = \frac{\pi N B^2 S^2 r}{\frac{r^2}{u} + 4\pi^2 u L^2},$$

wherefore it appears that K changes sign without changing value when u changes into $-u$. It has the value zero for $u = 0$, and also for $u = \pm\infty$; and it has a maximum numerical value when the two terms of the denominator, the product of which is constant, are equal to one another, or when

$$u = \pm\frac{1}{2\pi}\frac{r}{L}.$$

Meanwhile the line $C_1 C_2$ (Fig. 14), the points of which have for abscissa the values of u, and for ordinate the corresponding values of K, is composed of two branches similar with respect to the origin O. It passes through the origin, is asymptotic to both the parts of the axis of abscissa, and presents two points M M' of ordinate numerical maximum, which correspond to the abscissa $+\frac{1}{2\pi}\frac{r}{L}$ and $-\frac{1}{2\pi}\frac{r}{L}$. The value of the maximum is $\frac{\pi N B^2 S^2 u}{2}\frac{u}{r}$.

The origin O is a point of inflection, and in its vicinity the line cannot be distinguished from a straight line, the inclination of which is $\frac{\pi N B^2 S^2}{r}$. The abscissa of the maximum and minimum points M and M', and also the length of the part, which practically is indistinguishable from a straight line, increase with the diminution of $\frac{L}{r}$. At the limit, where $\frac{L}{r} = 0$, the points M and M' would be removed to infinity, and the line would be transformed into a straight line, passing through O, with the inclination

$$\frac{\pi N B^2 S^2}{r}.$$

Given the value of u, and maintaining L constant, the couple K varies with the resistance r. The law of the variation appears clear if we put the expression of K in the form

$$K = \frac{\pi N B^2 S^2 u}{r + \frac{4\pi^2 u^2 L^2}{r}}.$$

For $r = 0$ and for $r = \infty$ K is zero; for $r = \frac{4\pi^2 u^2 L^2}{r}$, or for $r = 2\pi u L$, it is at a maximum. The value of the maximum is $\frac{\pi N B^2 S^2 u}{2 r}$, as above. It may be noted that the value of r, to which corresponds the maximum of K, is proportional to the frequency u, of the relative motion between the field and the armature.

(*To be concluded.*)

THE WORK OF HERTZ.*

The untimely end of a young and brilliant career cannot fail to strike a note of sadness and awaken a chord of sympathy in the hearts of his friends and fellow-workers. Of men thus cut down in the early prime of their powers there will occur to us here the names of Fresnel, of Carnot, of Clifford, and now of Hertz. His was a strenuous and favoured youth; he was surrounded from his birth with all the influences that go to make an accomplished man of science—accomplished both on the experimental and on the mathematical side. The front rank of scientific workers is weaker by his death, which occurred on January 1st of the present year, the thirty-sixth of his life. Yet did he not go till he had effected an achievement which will hand his name down to posterity as the founder of an epoch in experimental physics.

In mathematical and speculative physics others had sown the seed. It was sown by Faraday, it was sown by Thomson and by Stokes, by Weber also doubtless, and by Helmholtz, but in this particular department it was sowed by none more fruitfully and plentifully than by Clerk Maxwell. Of the seed thus sown Hertz reaped the fruits. Through his experimental discovery, Germany awoke to the truth of Clerk Maxwell's theory of light, of light and electricity combined, and the able army of workers in that country (not forgetting some in Switzerland, France and Ireland) have done most of the gleaning after Hertz.

This is the work of Hertz which is best known; the work which brought him immediate fame. It is not always that public notice is so well justified. The popular instinct is generous and trustful, and it is apt to be misled.

The scientific eminence accorded to a few energetic persons by the popular estimate is more or less amusing to those working in the same lines. In the case of Hertz no such mistake has been made. His name is not over well known, and his work is immensely greater in every way than that of several who have made more noise. His best known discovery is by no means his only one. I have here a list of eighteen Papers contributed to German periodicals by him, in addition to the Papers incorporated in his now well-known book on electric waves. I would like to suggest that it would be an act of tribute, useful to students in this country,

* A lecture delivered at the Royal Institution on Friday, June 1st, by Prof. Oliver Lodge, F.R.S., ably assisted during both preparation and performance by Mr. Edward E. Robinson.

Digitized by Google

if the Physical Society of London saw their way to translate and publish a collection of, at any rate, some of these Papers.*

Portrait Slide.

The portrait (Fig. 1) which I show is not a specially pleasing one. It is from a photograph taken by Mr. Yule, one of the band of foreign students who flocked to Hertz's laboratory at Bonn. It is excellent as a photograph, though it fails to represent Hertz at his best; perhaps because it was not taken till after the pharyngeal trouble had set in, which ultimately carried him off.

In closing these introductory and personal remarks, I should like to say that the enthusiastic admiration for Hertz's spirit and character, felt and expressed by students and works who came into contact with him, is not easily to be exaggerated. Never was a man more painfully anxious to avoid wounding the susceptibilities of others; and he was accustomed to deprecate the prominence given to him by speakers and writers in this country, lest it might seem to exhalt him unduly above other and elder workers among his own sensitive countrymen.

Speaking of the other great workers in physics in Germany, it is not out of place to record the sorrow with which we have heard of the recent death of Dr. August Kundt, Professor in the University of Berlin, successor of von Helmholtz in that capacity.

When I consented to discourse on the work of Hertz, my intention was to repeat some of his actual experiments, and especially to demonstrate his less known discoveries and observations. But the fascination exerted upon me by electric oscillation experiments, when I, too, was independently working at them in the spring of 1888,* resumed its hold, and my lecture will accordingly consist of experimental demonstrations of the outcome of Hertz's work rather than any precise repetition of portions of that work itself.

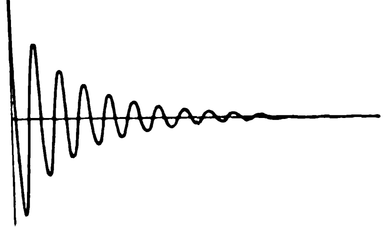

Fig. 2.

In case a minority of my audience are in the predicament of not knowing anything about the subject, a five minutes' explanatory prelude may be permitted, though time at present is very far from being "infinitely long."

The simplest way will be for me hastily to summarise our knowledge of the subject before the era of Hertz.

Just as a pebble thrown into a pond excites surface ripples, which can heave up and down floating straws under which they pass, so a struck bell or tuning-fork emits energy into the air in the form of what are called sound waves, and this radiant energy is able to set up vibrations in other suitable elastic bodies.

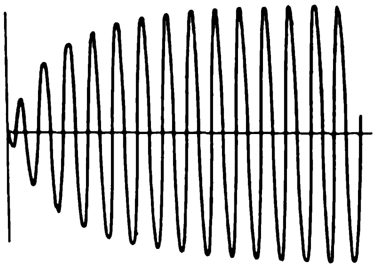

Fig. 3.

If the body receiving them has its natural or free vibrations violently damped, so that when left to itself it speedily returns to rest (Fig. 2), then it can respond fully to notes of almost any pitch. This is the case with your ears and the tones of my voice. Tones must be exceedingly shrill before they cease to excite the ear at all.

If, on the other hand, the receiving body has a persistent period of vibration, continuing in motion long after it is left to itself (Fig. 3) like another tuning-fork or bell, for instance, then far more facility of response exists, but great accuracy of tuning is necessary if it is to be fully called out; for if the receiver is not thus accurately syntonised with the source, it fails more or less completely to resound.

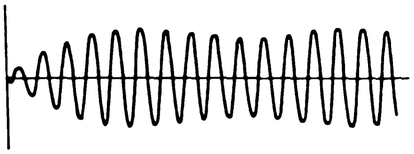

Fig. 4.

Conversely, if the *source* is a persistent vibrator, correct tuning is essential, or it will destroy at one moment (Fig. 4) motion which it originated the previous moment. Whereas, if it is a dead-beat or strongly-damped excitor, almost anything will respond equally well or equally ill to it.

What I have said of sounding bodies is true of all vibrators in a medium competent to transmit waves. Now a sending telephone or a microphone, when spoken to, emits waves into the ether, and this radiant energy is likewise able to set up vibration in suitable bodies. But we have no delicate means of directly detecting these electrical or etherial waves, and if they are to produce a perceptible effect at a distance, they must be confined, as by a speaking tube, prevented from spreading, and concentrated on the distant receiver.

* *Phil. Mag.*, XXVI. pp. 229, 230 August, 1888; or "Lightning Conductors and Lightning Guards" (Whittaker), pp. 104, 105; also *Proc. Roy. Soc.* Vol. L. p. 27.

Digitized by Google

This is the function of the telegraph wire; it is to the ether what a speaking tube is to air. A metal wire in air (*in function*, not in details of analogy) is like a long hollow cavity surrounded by nearly rigid but slightly elastic walls.

Sphere Charge from Electrophorous.

Furthermore, any conductor electrically charged or discharged with sufficient suddenness must emit electrical waves into the ether, because the charge given to it will not settle down instantly, but will surge to and fro several times first, and these surgings or electric oscillations must, according to Maxwell, start waves in the ether, because at the end of each half swing they cause electrostatic, and at the middle of each half swing they cause electromagnetic effects, and the rapid alternation from one of these modes of energy to the other constitutes etherial waves.* If a wire is handy they will run along it, and may be felt a long way off. If no wire exists they will spread out like sound from a bell, or light from a spark, and their intensity will decrease according to the inverse square of the distance.

Maxwell and his followers well knew that there would be such waves; they knew the rate at which they would go, they knew that they would go slower in glass and water than in air, they knew that they would curl round sharp edges, that they would be partly absorbed but mainly reflected by conductors, that if turned back upon themselves they would produce the phenomena of stationary waves, or interference, or nodes and loops; it was known how to calculate the length of such waves, and even how to produce them of any required or predetermined wave-length from 1,000 miles to a foot. Other things were known about them which would take too long to enumerate: any homogenous insulator would transmit them, would refract or concentrate them if it were of suitable shape, would reflect none of a particular mode of vibration at a certain angle, and so on, and so on.

All this was known, I say, known with varying degrees of confidence, but by some known with as great confidence as, perhaps even more confidence than, is legitimate before the actuality of experimental verification.

Hertz supplied the verification. He inserted suitable conductors in the path of such waves, conductors adapted for the occurrence in them of induced electric oscillations, and to the surprise of everyone, himself doubtless included, he found that the secondary electric surgings thus excited were strong enough to display themselves by minute electric sparks.

Syntonic Leyden Jars.

I shall show this in a form which requires great precision of tuning or syntony, both emitter and receiver being persistently vibrating things giving some 30 or 40 swings before damping has a serious effect. I take two Leyden jars with circuits about a yard in diameter, and situated about two yards apart (Fig. 5). I charge and discharge one jar, and observe that the surgings set up in the other can cause it to overflow if it is syntonised with the first.†

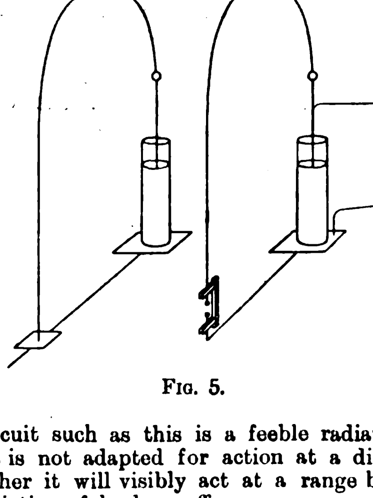

Fig. 5.

A closed circuit such as this is a feeble radiator and a feeble absorber, so it is not adapted for action at a distance. In fact, I doubt whether it will visibly act at a range beyond the $\frac{1}{4}\lambda$ at which true radiation of broken off energy occurs. If the coatings of the jar are separated to a greater distance, so that the dielectric is more exposed, it radiates better; because in true radiation the electrostatic and the magnetic energies are equal, whereas in a ring circuit the magnetic energy greatly predominates. By separating the coats of the jar as far as possible we get a typical Hertz oscillator (Fig. 6), whose dielectric extends out into the room, and this radiates very powerfully.

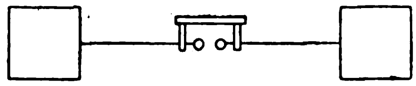

Fig. 6.

Ordinary Size Hertz Vibrator.

In consequence of its radiation of energy, its vibrations are rapidly damped, and it only gives some three or four good strong swings. Hence it follows that it has a wide range of excitation, *i.e.*, it can excite sparks in conductors barely at all in tune with it.

The two conditions, conspicuous energy of radiation and persistent vibration electrically produced, are at present incompatible. Whenever these two conditions coexist, considerable power or activity will, of course, be necessary in the source of energy. At present they only coexist in the sun and other stars in the electric arc and in furnaces.

Two Circular Vibrators sparking in sympathy.

The receiver Hertz used was chiefly a circular resonator, not a good absorber but a persistent vibrator, well adapted for picking up disturbances of precise and measurable wave-length. I find that the circular resonators can act as senders too; here is one exciting quite long sparks in a second one.

Electric Syntony.—That was his discovery, but he did not stop there. He at once proceeded to apply his discovery to the verification of what had already been predicted about the waves, and by laborious and difficult interference experiments he ascertained that the previously calculated length of the waves was thoroughly borne out by fact. These interference experiments in free space are his greatest achievement.

He worked out every detail of the theory splendidly, separately analysing the electric and the magnetic oscillation, using language not always such as we should use now, but himself growing in theoretic insight through the medium of what would have been to most physicists a confusing maze of troublesome facts, and disentangling all their main relations most harmoniously.

Holtz Machine, A and B Sparks; Glass and Quartz Panes in Screen.

While Hertz was observing sparks such as these, the primary or exciting spark and the secondary or excited one, he observed as a bye issue that the secondary spark occurred more easily if the light from the primary fell upon its knobs. He examined this new influence of light in many ways, and showed that although spark light and electric brush light were peculiarly effective any source of light that gave very ultra-violet rays produced the same result.*

Wiedemann and Ebert, and a number of experimenters, have repeated and extended this discovery, proving that it is the cathode knob on which illumination takes effect; and Hallwachs made the important observation, which Righi, Stoletow, Branly, and others have extended, that a freshly-polished zinc or other oxidisable surface, if charged negatively, is gradually discharged by ultra-violet light.

It is easy to fail in reproducing this experimental result if the right conditions are not satisfied; but if they are, it is absurdly easy, and the thing might have been observed nearly a century ago.

(To be continued.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

TO-DAY (FRIDAY), June 8th.

PHYSICAL SOCIETY.

5 p.m. (1) Discussion of the Paper by W. Baly and Prof. Ramsay "On the Relations of Pressure, Volume, and Temperature of Rarefied Gases;" (2) An Exhibition of Photographs of Flames by Capt. Abney.

ROYAL INSTITUTION.

9 p.m. Friday Evening Discourse: "The Newtonian Constant of Gravitation," by C. Vernon Boys, F.R.S.

WEDNESDAY, June 13th.

ROYAL SOCIETY.

Ladies' Conversazione.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

* Strictly speaking, in the waves themselves there is no lag or difference of phase between the electric and the magnetic vibrations; the difference exists in emitter or absorber, but not in the transmitting medium. True radiation of energy does not begin till about a quarter wave-length from the source, and within that distance the initial quarter period difference of phase is obliterated.

† See *Nature*, Vol. XLI., p. 368; or J. J. Thomson, "Recent Researches," p. 395.

* The experiments shown in the lecture was on the lines of those described in my book, "Lightning Conductors," pp. 314 and 340; the connections being much as on p. 285, or as depicted in *Proc. Roy. Soc.* Vol. L. p. 4.

HERTZIAN WAVES AT THE ROYAL INSTITUTION.

The triple task which Dr. OLIVER LODGE set himself to perform on Friday evening last at the Royal Institution was no easy one; to discourse upon "The Work of HERTZ," to perform a number of delicate experiments, and to interest a large and mixed audience. Many who were present would have been well content to listen to Dr. LODGE for an hour on the main subject of his discourse, with only a diagram or two to illustrate his words. The notes which he so soon laid aside were, however, only to be held over, for we are enabled to print a first instalment of them in our present issue. The experiments were performed under very unfavourable conditions; although Dr. LODGE confined himself to qualitative results, and, with one exception, made no attempt at producing waves of definite length, the effects were not perhaps as clearly demonstrated as was possible in the short time at his disposal. How much was due to the fact that the receivers were of a very sensitive kind, and liable to be disturbed by Hertzian waves of any character, how much to the undue strength of the oscillators, and how much to the very lively kind of galvanometer, it is difficult to say. Some of the experiments were evidently very difficult to carry out in a popular lecture; but there can be no doubt that many of them would have been much more successful with a tolerably dead-beat galvanometer, and there was no apparent reason why an aperiodic instrument could not have been used in these instances. Those of the audience who had some acquaintance with the subject were aware that the wave-length used in HERTZ's own experiments was considerable, and that not only very large prisms and reflectors were needed, but large halls and open spaces were also necessary. It is, however, clear that the experiments have now become more manageable, and some of them, at all events, may be repeated with the most homely apparatus. This important improvement introduced into the experiments consists in using oscillators giving waves of much shorter wave-length than those used by HERTZ. Dr. LODGE was the first to use spheres

Digitized by Google

as electric oscillators, and to show that the waves they gave rise to were shorter than could be easily obtained by the ordinary forms of oscillator. The advantage of using them to reproduce Hertz experiments on reflection, refraction, lens action, polarisation, &c., arises from the fact that if the wave-length of the oscillations is large, the mirrors, lenses, and prisms used have to be enormous, whereas Dr. Lodge has succeeded in reducing his apparatus to reasonable dimensions for a lecture-room. The oscillating sphere and the sparking apparatus were completely enclosed in a wooden box lined with tinfoil, the waves set up being only allowed to escape in a particular direction through a circular aperture in front. In this way a new form of electric lantern was constructed and exhibited for the first time. The waves projected from it were invisible, and could traverse solid walls. They cannot, therefore, be called light waves, but they can be focussed by an ordinary glass lens, reflected, polarised, and subjected to all the treatment of which light rays are capable. It is highly probable, as Dr. Lodge suggested, that Hertzian phenomena may have often manifested themselves in physical laboratories to the annoyance of workers, and it is well known that several experimenters (Edison amongst others) have actually observed them, but were unable either to account for them or to follow them up and intelligently examine them. Two carbons placed close together, but not actually touching, were connected with the mains of an electric-light circuit. Directly sparking was caused at a large Hertz oscillator hung up on the wall of the lecture-room, the arc was struck owing to the surgings set up in the carbons, causing a minute spark to pass between them, and thus starting the arc. This experiment has a practical interest, owing to the fact that electric light leads for glow lamps are generally twisted together, so that the copper wires are quite close. If the surgings caused by any electric disturbances in the neighbourhood are sufficient to give rise to a minute spark between the adjacent wires, an arc will form and the fuse will go, even if nothing worse happen. It is possible, then, some cases of assumed short circuit have been really caused in this manner. It is not, however, probable that such cases have often occurred, but it is worth while pointing out that if the positive and negative leads of a building were so laid as to be separated for some distance before being brought near together at the lamps, such cases might be frequent. Adjacent parts of two wires laid parallel and close together tend to be at the same potential, whatever the character of the electric waves impinging on them. It will be remembered that several rules for wiring order that wires shall be laid at a considerable distance apart. The Phœnix rules propose a distance of 6in. to 12in. between primary conductors of high-pressure alternate-current supply; the 7th rule of the Institution of Electrical Engineers says: "Conductors should be kept as far apart as circumstances will permit, the spacing between them being governed by their potential difference." It is the universal neglect of this rule which probably protects ordinary house wiring from danger due to such a cause.

The comparative lack of enthusiasm which, however, characterised the Royal Institution gathering last Friday, the vast scientific potentialities and extreme beauty of Dr. Lodge's experiments notwithstanding, shows once more that a mixed gathering requires its doses of science to be dashed with theatrical effect. Most of us still retain a vivid and pleasing recollection of the Nikola Tesla lecture. Who could fail to be carried away by the ingenuous enthusiasm of the lecturer, or remain unimpressed in face of the weird waving of glowing tubes in the suitably darkened room, and the mysterious voice issuing from the midst of an electrostatic field? Such scenic setting prepared us for the subsequent unqualified success with a Royal Institution audience. It is not, of course, desirable that these Friday evening discourses should, as a rule, be tinged with quite so much of the dark *séance* style, but it is, we think, much to be desired that the lecturers should not altogether forget "the deep infinitude of nescience" around them. For instance, had it been impressively and reiteratedly brought home to the spectators last Friday evening that what they were witnessing in the experiment necessarily involving so much shouting but resulting in a minimum of sparking, was the transmission of electromagnetic waves right through three brick walls and across the staircase and the room adjoining the theatre, it is possible that even the most uninitiated would have left the Royal Institution that night with a tolerably concrete idea of the importance of the experiment. To Maxwellians, no doubt, the opacity of stone walls to such ether disturbances would be a far more astonishing phenomenon than their transparency. But the majority of mankind, and even indeed of those who gather together at the Royal Institution on a Friday evening, are not Maxwellians, and they, not unnaturally, would find much food for reflection in the transparency of a wall to Hertzian waves; the every-day opacity of a brick wall being to them a matter of so-called "common knowledge." After all, these lectures are largely intended as a pleasant means to a highly respectable end—to wit, the permeation of the intellectual public with a lively interest in the latest births of science. To that end a clear idea of the import of the experiments greatly conduces.

THREE MUNICIPAL SUPPLY STATIONS.

There are points about the municipal electric supply stations at Portsmouth, Burton, and Derby which render it probable that some interest and instruction may follow from a comparative study of them. In many respects all three of these stations are departures from the usual, almost stereotyped pattern of design into which modern English central stations seem to have fallen. It is not frequently that the rambler among supply stations discover points of very striking novelty. He generally finds himself surrounded, in the boiler house, with water tube boilers; in the engine room, with the so-called steam dynamos or alternators, with a well-known type of steam engine driving one or the other of well-established types of electric generators. Nor, if he examines a little more closely, does he discover any very much less similarity about the details. We are not wishing to convey the idea that crystallisation of design is a deplorable feature of modern electric supply stations. Far from it; for it is in the natural course of events that ripening experience should lead the electrical engineer to eliminate untrustworthy patterns, and to fall into the groove of one or the other of the lines of design which are considered to be the most successful. Nevertheless, novelty of design, however risky on the part of the engineer, is refreshing to the visitor and student.

We shall make no apology for not entering into a full categorical account of the plant to be found at each of the three stations we are now studying, nor for taking the various items together, instead of describing each system from the office door-handle to the terminals of the remotest consumer. Inventories of cocks, cables, and coal bunkers have their place and value. Mere photographs of engine rooms probably have a fascinating effect on a vestryman who thinks that they tell him everything; unfortunately, they tell the engineer little or nothing. We must refer our readers to other sources than our columns if they seek such information. The real interest attaching to these three stations lies in one or two details of design, rather than in the general outline. Certain interest also attaches to two of them on account of the fact

Digitized by Google

that they have been formally "inaugurated" only during the past week. The dinner given by the contractors, Messrs. Fowler and Co., to the Corporation of Burton took place last Friday, and the official opening of the Portsmouth station by the Mayor of that town occurred last Wednesday. The Derby station was opened on October 10th of last year, but in many respects it may be regarded as practically a new station.

At Portsmouth, Mr. Ferranti has been led to introduce such numerous and radical departures from any practice at other stations, that electrical engineers will watch with great interest the result of his fearless and original designs. Before considering these let us devote a little space to the mechanical plant. The general arrangement of the plant is shown in the accompanying plan of the station, Fig. 1, for which we are indebted to the consulting engineers, Messrs. Kincaid, Waller and Manville. Lancashire boilers, by Messrs. Yates and Thom, supplied with cheap bituminous slack by Vicars' mechanical stokers, are used, and the publication of their performance after some months of

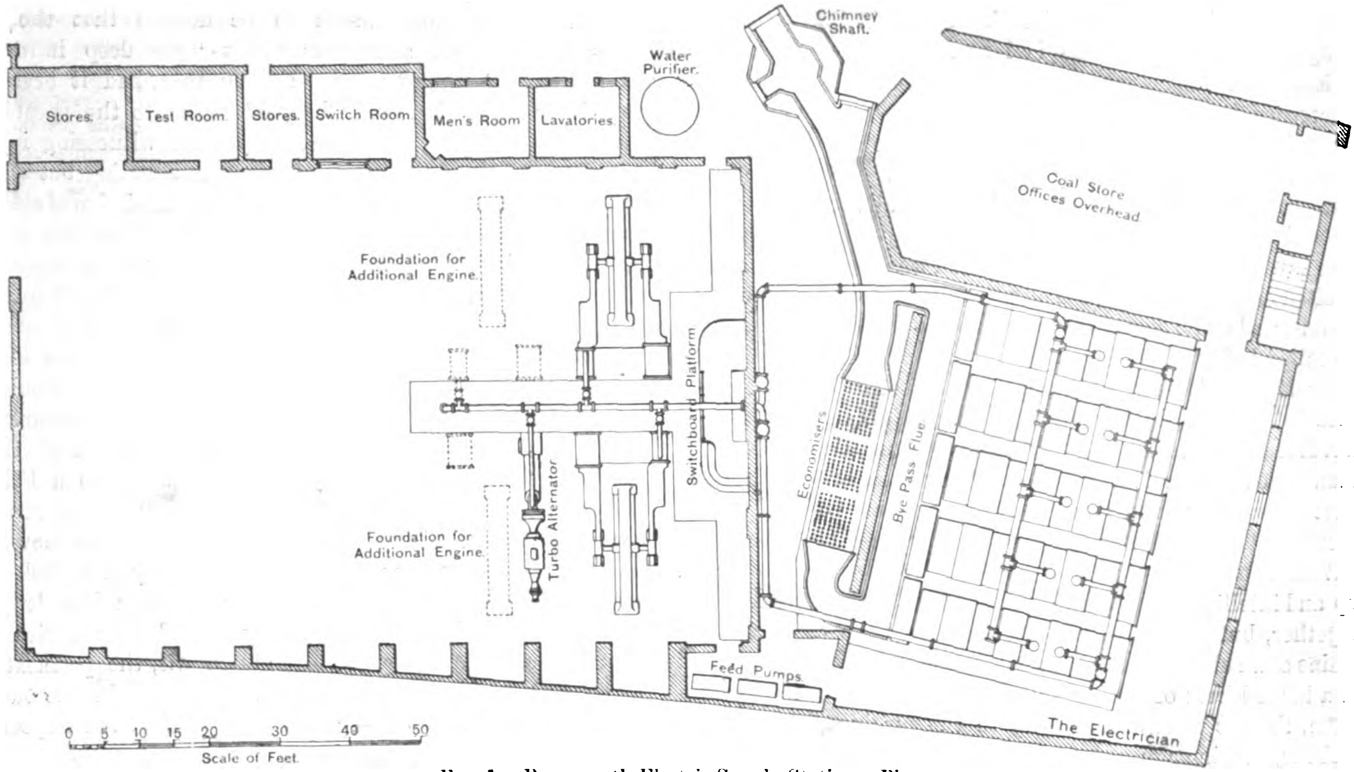

FIG. 1.—Portsmouth Electric Supply Station. Plan.

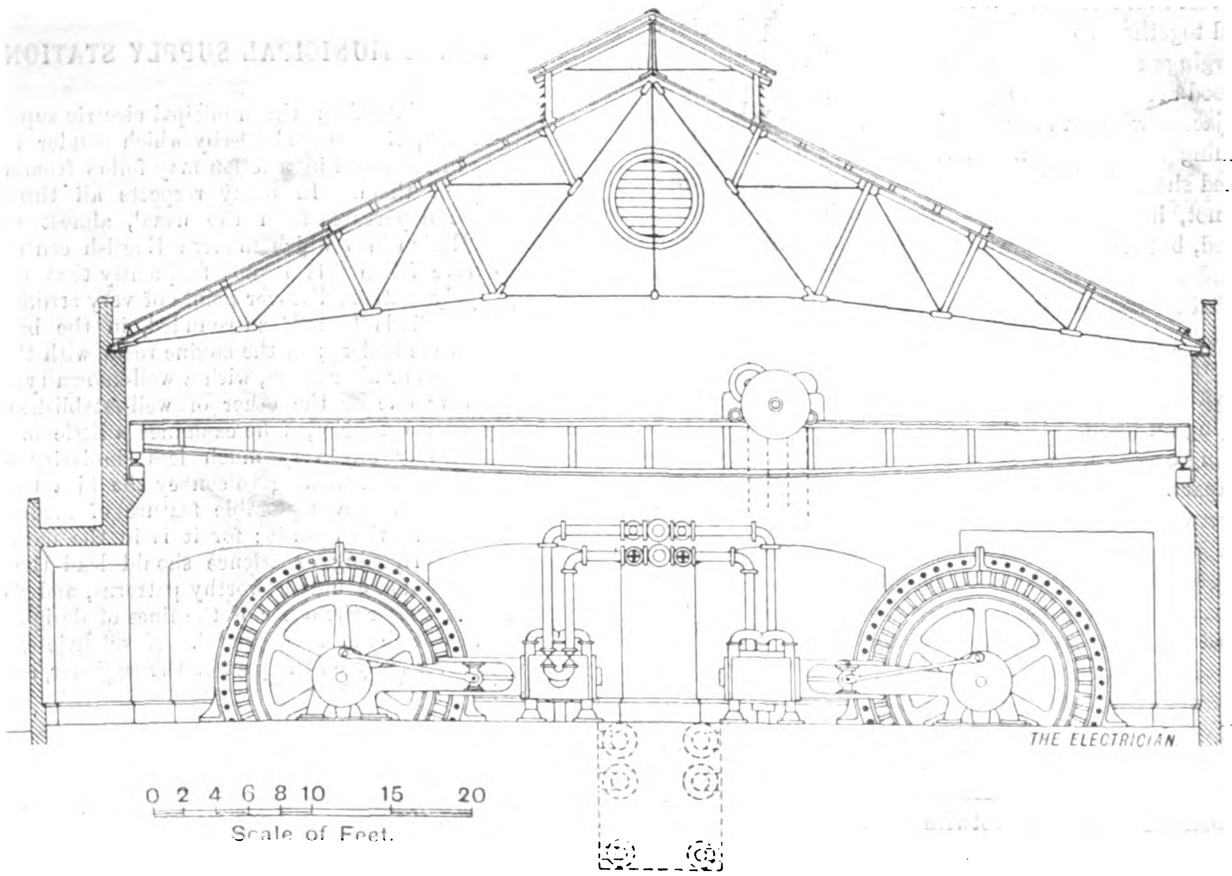

FIG. 2.—Transverse Section of Engine Room, Portsmouth.

Digitized by Google

work will be awaited with interest. In the system of steam mains there is undoubted safety, but it is not so certain that there is economy. Each boiler and each engine has a duplicate connection with the steam range; but the length of steam pipe is much longer, in proportion to the capacity of the station, than at Manchester, where a much more efficient system of Tee duplicate steam mains is used. We are in accord with some leading engineers, who have designed important stations, in doubting whether, in this mania for duplication of plant, especially of steam ranges, the insurance of safety is worth the loss of economy. One such engineer recently expressed to us the opinion that it would be far more advisable to put the amount of money that would be spent on duplicate mains into a single main of extraordinary reliability. The engines are horizontal, side-by-side, compound condensing steam engines, by Messrs. Yates and Thom, with cranks at 90deg., and Corliss valves and gear. The condensers and pumps are underneath the engines. The condenser pumps are operated by rods driven from the crosshead of the low pressure piston-rod. Owing to the impurity of the harbour water, town water is used for feeding the boilers, but harbour water is employed for the condensers. Nevertheless, strange to say, jet condensers are used, and the whole of the heat from the exhaust steam is ejected into the harbour. Accordingly, the feed water, before it enters the economiser, has to be warmed with live steam from the boilers.

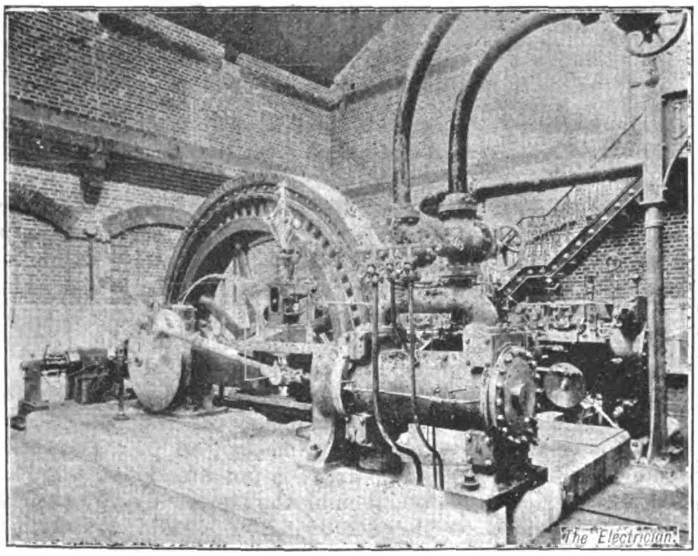

Fig. 3.—212-kilowatt Ferranti Flywheel Alternator.

Following the lines of his Continental practice, Mr. Ferranti has introduced into Portsmouth direct-driven alternators of low speed and low frequency. The speed of the two machines now in Portsmouth station is 96 revolutions per minute, and the frequency is 50 periods per second. This design gives a relatively larger unit of plant than is usual, owing to the necessity for a large diameter of the coil circles. Fig. 2 shows these two alternators in elevation, and Fig. 3 gives a perspective view of a corner of the engine room occupied by one of these units of plant. The armature of this alternator is fixed, and the field rotates. The axes of both armature and field coils are radial; and the magnetic field is reversed in the armature, not merely varied between zero and a maximum. The field coils are of bare copper strip, with the metal exposed to the air of the engine room, the successive layers of strip being insulated by means of thin vulcanised cloth. The copper strip for these coils is drawn and wound exactly in the shape required to fit the coils. The armature coils are wound through thin iron stampings, which form the core. These stampings are segmented in shape, as shown in Fig. 4, and they fit into the coil circle so as to expose only a continuous metal face towards the revolving field poles. The clearance between the armature and field poles is $\frac{3}{16}$in., but as the surfaces are both practically of solid metal this small clearance involves no risk of injury. In Fig. 4, the circular hole is for the bolt by which the stampings are clamped together and to the cast-iron frame of the armature; and the windings are passed through the oblong holes in the lower part. A word or two about the alternators at Burton will here be of interest, and will enable the reader to compare the two types. In the "Leeds and London" alternators, erected by Messrs. Fowler and Co. at Burton, the revolving field-magnets are arranged as shown in Fig. 5, while the armature coils and core are as illustrated in Figs. 6 and 7. Fig. 6 shows the interior surface of the armature circle, and Fig. 7 the exterior surface; it will be noticed that the armature coils are not "hole-wound," as at Portsmouth, but are exposed on the inner surface of the armature circle.

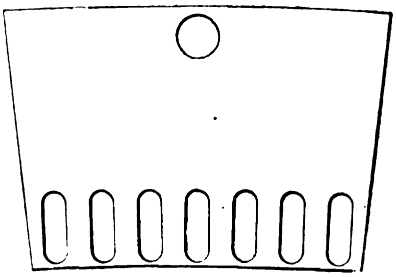

Fig. 4.

At present there are, at Portsmouth, two 212-kilowatt alternators of the new Ferranti type, which, together with a 150-kilowatt Parsons' steam-turbine alternator, make up the complement of generators at this station. What the effect of such relatively large units of plant upon the economy will be, remains to be seen; but considerable increase of the load must take place before a single unit can be run all day with nearly full output. The alternators, whenever more than one is required, will be run in parallel, all the generators feeding the same pair of bus bars. The switchboard arrangements are

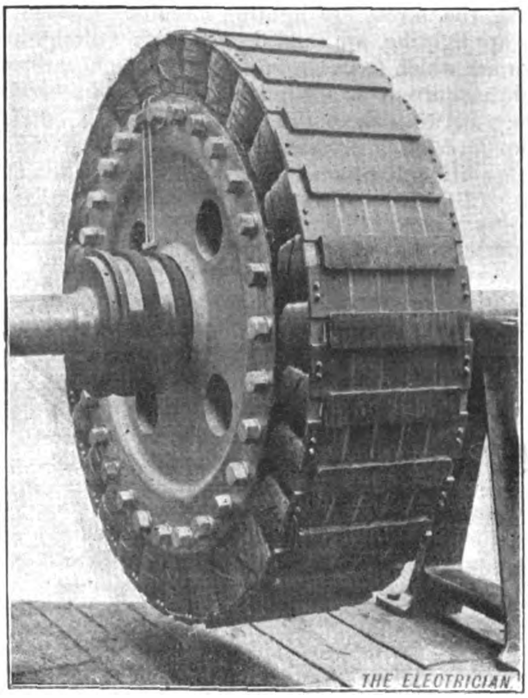

Fig. 5.—Alternator Field Magnets, Burton.

unique. Each machine has only one switch, each circuit has a similar number. The pole of the machine, or the main feeder, not connected to this switch is *permanently earthed* at the station. This ensures that the particular detail thus earthed shall be permanently at zero potential. All the cables are concentric, the outer conductors being earthed in the manner described. The feeders supply a network of high-pressure mains, on which the primary coils of the transformers are placed. The secondary coils feed the low-pressure network. In putting any one machine on to the circuit, the switch belonging to it is first raised into an intermediate

Digitized by Google

or "half-cock" position. In this position it is synchronised, after which it is snapped over to "full-cock," *i.e.*, on to the bus bars. The pressure of the machine is regulated by means of rheostats in the exciting circuit, and the rheostat handle is formed into the shape of a circular ring placed round the exciter ammeter, and so arranged that while reading the ammeter the hands may be used for adjusting the rheostat to which the particular ammeter belongs. This, as well as every other detail in the switchboard design, is introduced for the purpose of simplifying manipulation and rendering mistakes

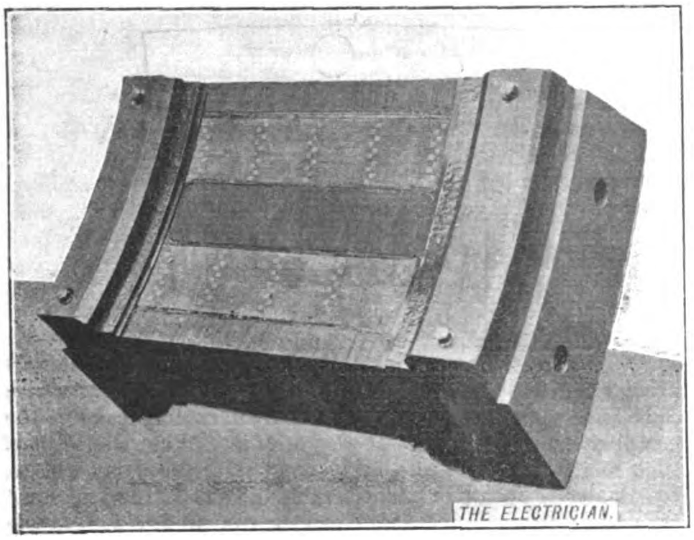

Fig. 6.—Portion of Alternator Armature, Burton.

as nearly impossible as can be. The main switchboard is 6ft. wide and about 3ft. 6in. deep, and controls the entire system, including the street arc lighting circuits. Concentric mains for the arc lighting are carried from this switchboard to the transformer which feeds the special arc switchboard, where the arc lighting current is subdivided among the several arc lamp circuits. Between these two switchboards the current undergoes two interesting processes of change: (1) It is converted from a condition of constant pressure to a condition of constant current; (2) it is rectified from an alternating current to an

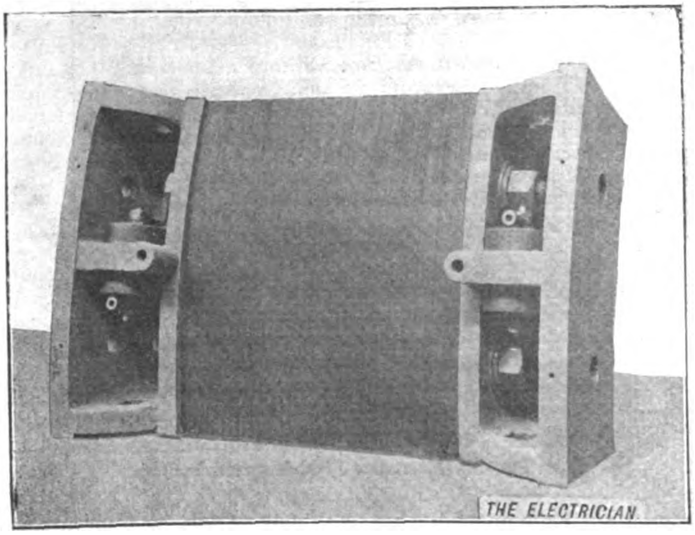

Fig. 7.—Portion of Alternator Armature, Burton.

unidirectional intermittent current of nearly harmonic variation. The first-named change is effected by means of a transformer, which is so designed that the secondary induced electromotive force shall vary directly with the load, *i.e.*, with the number of arc lamps in series in the circuit. The action of this transformer may be explained by reference to Fig. 8. The middle coil, B, is fixed to the frame of the transformer; the upper and lower coils, A and C, are movable and their weight is opposed to a counterpoise on a lever. When no current passes through the middle coil, or when the circuit of the two outer coils, which form the secondary coil, is open, the weight of the counterpoise causes them to come into contact with the middle coil. But, if the secondary circuit is closed by a number of arc lamps in series, and if an alternating current is now sent through the middle coil, the secondary induced current will be repelled by the primary current, and the movable coils will move away from the middle coil until the electromagnetic force just balances the difference between their weight and that of the counterpoise. In this position of equilibrium, which, whatever the load on the circuit, is one of constant electromagnetic force, there must be just sufficient magnetic induction through the two outer coils to induce in them an electromotive force which will develope the requisite current in the arc circuit. Since the force exerted is constant in all positions when the machine has once been adjusted, the induced current will be constant at all loads. The machine is a leaky transformer, designed to vary its leakage (has not

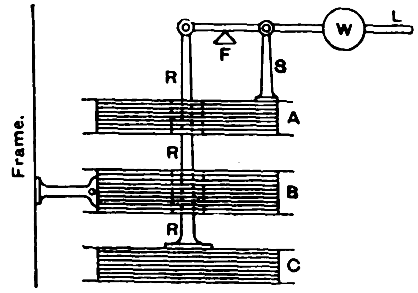

Fig. 8.—A and C = Secondary Coils. B = Primary Coil. W = Counterpoise. L = Lever. F = Fulcrum. S = Strut for A to L. R = Tie Rod supporting C.

someone called it "leakance"?) inversely with the load. The secondary current thus induced is now passed through a Ferranti rectifier, which comprises a synchronous alternate-current motor and a pair of commutators, after which it is taken to the arc switchboard. A front view of one of these rectifiers is shown in Fig. 9. The form of the current given by the rectifier is illustrated in Fig. 10; and it is found that the intermittence and absence of steadiness of the current promotes steadiness of the arc light, by keeping the lamp regu'ating mechanism in a perpetual state of agitation. As the current is uni-directional, a crater is formed on the positive carbon of the lamp. By means of a direction-indicator on the arc switchboard, and a reversing

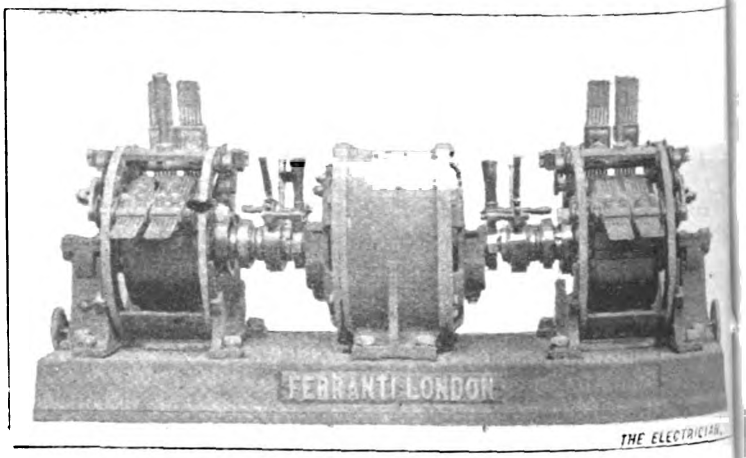

Fig. 9.—50-Light Ferranti Alternate-Current Rectifier.

switch, it can be arranged that the crater is formed on the top carbon, thereby obtaining the advantageous distribution of light which has hitherto been the exclusive possession of the continuous current arc. We do not remember to have seen more steady nor better distributed arc light than we saw at Portsmouth a few days ago during a trial of the various circuits. It is also worth mentioning that the low frequency of the alternations—adopted in order to render motor work more simple—has no injurious effect upon the light. The method

Digitized by Google

of wiring the arc lamps to the concentric arc-light cables is shown in Fig. 11, and possesses some novel features. It will be seen that the lamp leads are all connected to the outer conductor of the cable, which conductor alone is severed. The inner conductor and the insulation separating it from the outer are not disturbed. This arrangement is designed to give high insulation resistance. As many as 50 arc lamps may be wired to the same cable, the highest number at present being 37. Two cables are usually run in series on a single rectifier.

The new Ferranti transformers merit a few words of description. These are placed in street transformer pits, as at Scarborough, Derby, and Burton; but they differ from any of the latter in that they are arranged so that they may be adjusted either for full or half load. The adjustment is made by means of a key, carried round the circuit by a man; and by means of this key two coils on the primary portion of the winding may be put either in series or parallel, and simultaneously two coils

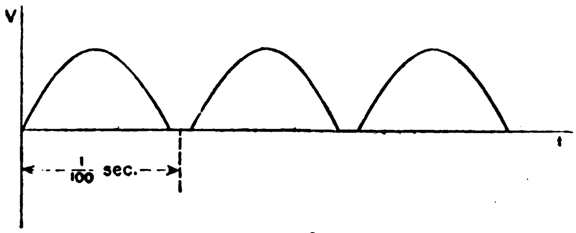

FIG. 10.

on the secondary portion are similarly coupled. When the load is high, both sets of coils are placed in parallel; when the load is low, both sets are put in series. At Burton, also, the practice of turning off and on the transformers by means of a key has been introduced; but the transformer is either wholly on or wholly off. At low loads there are fewer transformers on the high-pressure network. We understand that it is the intention of the contractors at both places ultimately to introduce some system of automatic or electric control of the transformers, in place of sending a man round with a key. Perhaps, however, the prosaic method of sending the man may be found to give sufficient satisfaction, indeed the main difference between the automatic and the manual method will probably be found to lie in the fact that the one will frequently stick while the other will occasionally strike.

Burton electric supply station derives considerable advantage from the fact that both it and the gas works are under the control of the municipality; besides which, the two works are

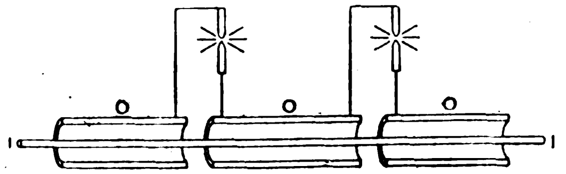

FIG. 11.—I = Inner Conductor. O = Outer Conductor.

next-door neighbours. Owing to this arrangement, the electric plant obtains fuel for nothing, and the gas works gets rid of its refuse—in the shape of this fuel—for a like figure. The fuel consists chiefly of dirty coke breeze. Plenty of it is required in order to produce a small quantity of steam; but, we understand, the Corporation used to pay a considerable sum to get rid of the material, before the commencement of the electric supply. The class of fuel is just such as might advantageously be stoked mechanically; but hand firing has been adopted, and stoking must constitute a considerable item of the works costs. Like Portsmouth, the Burton station lies close to a supply of natural water which might be used for condensing. Condensers have not been introduced, however. The existing generating plant is laid down on the lines of the plant supplied by the same firm to the Brompton and other "House-to-House" stations; but we are informed that in making extensions Messrs. Fowler and Co. intend to abandon rope-driven alternators, and to introduce a type of direct-driven fly-wheel alternator of their own design.

Little space remains to us to make any remarks on the electric supply station at Derby. This station resembles the other two in many respects; it also differs in some important details. Alternating current of a frequency of 40 periods per second is employed for the general supply, and continuous current for the street arc lighting. We need not enter into any consideration of the purpose which the consulting engineers could have had in view in specifying so low a frequency, but it is worth remarking that in some temporary arc lighting which we saw while in Derby recently, the arcs being run on the alternate current circuit, there was a perceptible, not to say painful, flicker of the light, due to the low frequency adopted. This makes it probable that arc lighting in shops will not be popular in Derby.

The mechanical plant at Derby comprises Lancashire boilers, mechanically stoked—as at Portsmouth—and high-speed steam engines, direct coupled to the dynamos and alternators. The engines are of the open type, inverted, vertical, compound condensing, varying from 50 to 100 H.P. They appear to have this disadvantage, as compared with the enclosed type, that they splash large quantities of oil about the engine room. Surface condensers are used, the condensing water being too impure for feeding the boilers. The electrical plant comprises 2,000-volt alternators for the general supply, and continuous-current machines for the arc lighting. Transformer sub-stations are used, the transformers being placed in street boxes, many of which are immediately below the arc lamp standards. There is no provision for cutting transformers out of the circuit on light loads. Each transformer has a capacity of about 1,200 lamps of 8 c.p. The secondary circuit consists of a 105-volt ring main, with numerous cross-connections for equalising the pressure over the entire system.

ELECTRIC TRACK WELDING AT ST. LOUIS.*

BY RICHARD M'CULLOCH.

To build a track which would obviate the ceaseless trouble with joints, and to perpetually insure a smooth and easy riding roadbed, was the object of the management of the Baden and St. Louis Railroad when, last February, it closed a contract with the Johnson Company to weld together the rail ends of its reconstructed road. In the past few years there have been several experiments with continuous track, and all tend to show that the difficulties which would be supposed to arise from contraction and expansion can be neglected. The most scientific and thorough experiment along this line was made by A. J. Moxham, president of the Johnson Company, early in 1892, and reported to the American Street Railway Association, at Cleveland, in that year. In this case the rails were so bolted together as to be practically continuous. Previous to this Philip Noonan laid some track with hot riveted rail joints, on the Lynchburg and Durham Railroad, near Gladys, Va. Some time ago C. W. Wason, of the Cleveland Electric Railway, laid some track with hot riveted rail joints. All of these trials gave satisfactory results. Last year the Johnson Company, having procured a suitable electric welder from the Thomson Electric Welding Company, several miles of track were welded on the West End road, of Boston. There was some trouble from rails breaking near the welds, but the Johnson Company persevered with its experiments and entered the field this year prepared to guarantee its work. Street railways have shown a great willingness to try welded track, and this season will be one of great activity along this line. The road under consideration is the first to begin welding operations this season.

The Baden and St. Louis Railroad is one of the oldest street railways in St. Louis, its charter having been granted in 1870. The road was formerly operated as an independent horse road, having a single track with turn-outs, but as it has recently passed under the same management as the Broadway Cable, it was decided to operate the road by electric power and use it as an extension of the cable road. The road is about three and a-half miles long, and is to be double track the entire distance. There are no crossings with other roads, and although there are no sharp curves, it has a number of long bends of 800 to 2,000ft. radius. In making the sharper bends, the rails are curved in a rail bender and then welded in place. The street in which the track is laid is an old macadam road, varying in width from 60ft. to 80ft., and is used very much by farmers in bringing their produce to the city.

* From the *Street Railway Review*, of Chicago.

Digitized by Google

The terminus of the Baden road is about 2½ miles from the power house. Five No. 0000 wires are run from the station, four of them being overhead and one a track feeder. As there is no direct rail return to the power house, an additional track connection is secured in the following manner:—The terminal sheave of the cable is well bonded to the first rail of the new electric road, and at a point where the cable track crosses an electric track, the carrying pulleys of the cable are bonded to the rails of an electric road which runs directly to the power house. In this manner the cable and conduit act as return conductors.

Preparatory to the welding operation, it was found necessary to lay the track, tamp it, line it, and surface it completely before the joints were welded. At the start an attempt was made to weld the joints first and tamp and surface the track afterwards, but the weight of the welding car was such that the rail was bent down in the middle and raised at the ends, making joints welded in this manner high. The road-bed is first ploughed out to the necessary

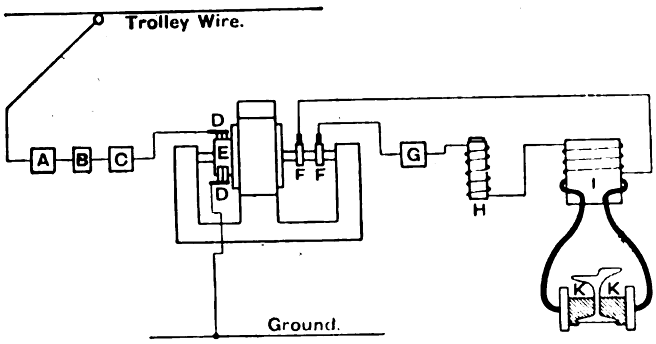

Fig. 1.—Diagram of Welding Circuit.

depth. Then 6in. of macadam are thrown in and rolled. Upon the rolled surface are placed the hewn white oak ties, 3ft. apart. The rails are then spiked to the ties, and the track tamped to grade and filled in to the tops of the ties. The rails are then ready for the welding of the joints.

The welding car is equipped with two W. P. 50 motors, with the rheostat, reversing switch, &c., of an ordinary street car. In addition to this it has the welding circuit shown in Fig. 1. The current from the trolley passes through an automatic circuit-breaker, switch, ammeter and starting rheostat to a transformer which transforms from the 500-volt continuous to an alternating current. This transformer resembles an ordinary four-pole general electric 100-kilowatt dynamo. To obtain the alternating current four leads from the windings are taken off at equal distances around the armature, and led to two collector rings on the

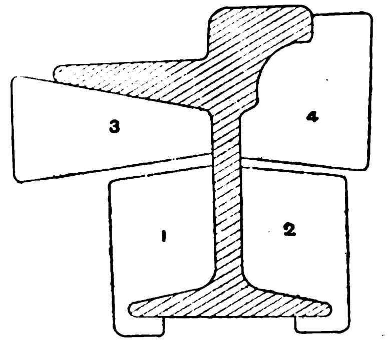

Fig. 2.—Lugs Welded to Rails.

armature shaft. The speed of the transformer is about 1,100 revolutions per minute, so that the periodicity of the alternating current is about 4,400 per minute. The alternating current from the collector rings passes through a regulating induction coil with a movable iron core to the welding machine. This machine is hung on a crane so that it may be set over either rail, and is simply an alternating-current transformer on a huge scale, in which the rail joint completes the secondary circuit. It was made by the Thomson Electric Welding Company, and operates on the same principle as its well-known machines. The insulation of the coils is paraffin oil, and the secondary consists of a single turn of an enormous bundle of sheet copper strips. These strips lead to two copper contact plates, between which the welding is done. The distance between the plates is controlled by a toggle joint operated by a screw, so arranged that by a slight turn of the screw a great pressure may be brought to bear upon the weld. In addition to this circuit, the welding car contains a motor for operating the crane, and another for driving a pump which circulates water in the welding machine. The car is very heavy, weighing about 30 tons when equipped for work. There is also a small car which carries two motors, operating emery wheels attached to flexible shafts for polishing the joints preparatory to welding.

The welded connection between the rails is made by means of lugs welded to the web of the rail. A section at the joint is shown in Fig. 2. It is intended that enough plastic steel shall enter the joint to make a butt weld, and that additional security be afforded by the lugs welded to the web. The bottom lugs, Nos. 1 and 2, are first welded. After they are in position, the operation is completed by welding Nos. 3 and 4. It requires from one to two minutes to make each weld. The potential at the welder is transformed down to four volts. The direct current transformer takes from the line about 250 amperes at 500 volts.

The operation of welding is as follows: The ends of the rails are butted together by driving a wedge in the joint ahead. The welding car is then run over the joint to be welded, and the welding takes place at the rear of the car, so that it is never necessary to run over a hot joint. The webs of the rails are polished with emery wheels for about two inches on each side of the joint. The joint is then clamped by means of a gunmetal casting, which holds the rails in proper position while the weld is being made. The bottom lugs (Nos. 1 and 2 in Fig. 2) are then placed in position and the contact clamps screwed down upon them. When the circuit of the secondary coil is thus completed, the switch on the welder is closed, and the iron core of the induction coil slowly raised. Almost instantly a dark, ruddy colour appears in the lugs, which gradually brightens until the welding heat is reached. A quick turn of the screw which operates the toggle joints brings the lugs firmly up against the rail and forces the plastic steel into the joint between the ends of the rails. The upper lugs (Nos. 3 and 4) are quickly inserted, the contacts raised and screwed down upon them, and they are welded in the same manner as the lower lugs. Pieces of carbon are previously placed upon the top of the rail, so that this portion is carbonised and hardened by the process. After the lugs are welded, the tread and flange are smoothed up by hammering. The welding has been so perfect in many instances, that after the track has been filled in it is impossible to see the joint in the tread.

The greater portion of the time is consumed in preparing the joints, moving the machine, setting up the welder, &c. The machine has been completing 30 to 50 joints per day of ten hours.

At the present writing no great trouble has been experienced from expansion and contraction. The temperature of the air has varied exceedingly. Several of the joints broke soon after welding, but these were probably imperfect welds. These joints were re-welded as soon as the break was discovered. No buckling has thus far been noticeable on the warmest days. The track is filled in as soon as possible after welding, but on several occasions, 300 to 500 feet of welded track have been left open for several days without bad results.

LEGAL INTELLIGENCE.

Grosvenor Hotel Company v. Hamilton.

This was an action before Lords Justices Lindley, Lopes and Davey, in the Court of Appeal, by the Grosvenor Hotel Company, for a quarter's rent in respect of certain premises in Buckingham Palace-road, London, of which the defendant was tenant under a lease. The defendant's case was that the plaintiff Company had placed certain pumping and electric light engines on land adjacent to the defendant's premises, and that the vibration caused by the working of the engines had so damaged his premises that they had been condemned by a magistrate as dangerous structures and ordered to be renovated and repaired. By preference the defendant removed his business, and accordingly counter-claimed for damages for the loss which he had sustained by the removal. It was proved at the trial that the premises in question were at the date of the lease (March 25, 1887) in an unstable condition, and were, in fact, 12in. out of the perpendicular. The original action was tried before Mr. Justice Grantham and a jury in April, and resulted in a verdict for the plaintiffs on the claim for £62 (the amount of the rent), and a verdict for the defendant on the counter-claim for £308. 5s., and judgment was entered accordingly. The plaintiffs now applied for a new trial as to the counter-claim, on the ground that the learned judge ought to have directed the jury that the plaintiffs would only be liable if the vibration was such as would have affected houses of ordinary stability, and also on the ground of excessive damages.

Lord Justice LINDLEY said that this was an action by a landlord against a tenant for rent. That was met by the defendant by a counter-claim to the effect that the plaintiff Company had, by working certain engines in connection with their hotel, shaken down his house. The vibration was so great that the tenant was obliged to leave, and his case was that he had thereby been put to unnecessary expense. It was said that the vibration would not amount to a nuisance unless it was sufficient to affect a house of ordinary stability. That might be so, as between strangers, but here the Court had to deal with the case of land,

Digitized by Google

lord and tenant, and the proposition of law which had been contended for assumed a different shape. The house when it was let was an old house and more or less delicate, as it was put by one of the witnesses, and it was several inches out of the perpendicular. That house had been shaken down by the landlord. How could it be said that there was no cause of action? The cause of action was nuisance, arising from the vibration which shook the house down, and one consequence of the relation existing between landlord and tenant was that the landlord was estopped from setting up, as against the tenant, that the house which he had let was a weak house. The true cause of action was nuisance. Then, as to the damages. The true principle to be applied was the principle which governed damages in an action of tort; and in such cases the injured party was entitled to recover damages for what were the natural consequences of the wrong. Their lordships were all of opinion that the damages awarded by the jury were too large, and that they ought to be reduced to £200.

With this modification, the application for a new trial was refused.

Alabaster and Others v. Harness.

This case came before Mr. Justice Hawkins and a Special Jury for trial in April last, and there was now further consideration of it in reference to the questions of law.

The plaintiffs had taken part in the discussion as to the Harness electrical belts, and in connection with this matter there had been litigation between them and Harness. In the plaintiffs' journal there also appeared a review of a pamphlet published by Dr. Tibbits, who had some connection with the defendant. Tibbits thereupon brought an action against the plaintiffs for libel in reference to some passages in that review, but the verdict and judgment in that case were for the present plaintiffs, with costs. The costs which these plaintiffs incurred were as between solicitor and client £596, and as between party and party £435. What plaintiffs now complained of was that the defendant had instigated Tibbits to bring that unfounded action of libel against them, and had thus put them to great expense in respect of costs, they being unable to get payment of their costs from Tibbits. On the other side it was contended that the plaintiffs had made out no case, that it had not even been shown that there was a common interest between Harness and Tibbits involved in the action of libel which the latter had brought against the plaintiffs. Without this being shown it was submitted that the plaintiffs could not maintain the present action for "maintenance."

Mr. DODD, for the defendant, submitted that there were two substantial questions, whether the defendant had a common interest with Tibbits in the libel suit against the present plaintiffs, and, if not, whether he believed that he had such interest. The facts were that Tibbits was retained by Harness as Managing Director of the Battery Company to make a report as to the electrical belt, and that report Harness published at his own expense or the expense of the Company, and distributed it broadcast. Then the writer of the pamphlet was attacked by the plaintiffs, and it was important to Harness to show that this report was unjustifiable and untrue. Under these circumstances it was submitted that the defendant clearly had a common interest with Tibbits in establishing against the present plaintiffs the action for libel upon the review of Tibbit's pamphlet.

On Wednesday Mr. Justice Hawkins heard further arguments, and, after pointing out that the question involved was one of general importance, and that his decision might be appealed against, reserved judgment.

Elmore's Wire Manufacturing Company (Limited).

As though the Elmore Companies had not been sufficiently unfortunate, the Wire Company has found it necessary to ask the Court of Queen's Bench to assist them in directing that a Bill presented by a Mr. A. T. Ashwell, formerly solicitor to the Company, should be taxed. The Company's application had been refused by the Judge in Chambers on the ground that the bill had been paid; but, notwithstanding this, Mr. Justice Cave, in the present action, said that, "looking at all the circumstances, the proper conclusion appeared to be that the payment of £500 made by the Company was not a settlement of the bill for which the Company now asked the Court to direct taxation, but a payment generally on account. The Company had complained of a number of irregular charges, it being stated by counsel that, as solicitor to the Company, Mr. Ashwell had attended a Board meeting, and had taken instructions to write to 20 shareholders for payment of calls, and the bill sent in, which the Company now wished to have taxed, contained 20 items of 6s. 8d. for taking these instructions, 20 items of 6s. 8d. for receiving the writ, and 20 items of 6s. 8d. for receiving instructions for appearance! No doubt some of these allegations of undue charges had been fairly explained away in the affidavits, but there were some items which it was reasonably to be supposed would be reduced by the taxing master; and further, there were admittedly several items wrongly inserted. Under the circumstances it would be best to send the bill for taxation, the costs in the application to abide the result.

Motors in Factories.—We hear that the Western Electric Company are fitting up their Chicago factory with separate electric motors to drive the various machine shops, thus obviating the necessity of having large belts and long shafting. The generating station in the Company's factory consists of two large Western Electric generators, connected to a high-speed engine.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 25, 1894.

The Annual Meeting of the American Institute of Electrical Engineers.—The annual and general meeting of the American Institute of Electrical Engineers at Philadelphia, last week, was the most successful in its history, both in attendance and sustained interest in its proceedings. About 250 members were in attendance, a large portion remaining during all four of the days that the meeting lasted. The address of the President, Prof. Houston (who was re-elected), was devoted to an historical view of the Institute which, with this meeting, entered into its second decade; to a consideration of the grounds upon which its usefulness depends; and to further extensions of its work. The desirability of co-operation with similar national bodies in Europe was dwelt upon, and the success of the experiment of local meetings as exemplified by that of Chicago was referred to as one of the notable events of the year. Of the papers, those on lightning arresters, toothed *versus* smooth core armatures, and test of closed coil arc light dynamo armatures, brought forth valuable practical discussions. There was an unanimity of opinion that arc light dynamo armatures should not be designed for an induction higher than about 16,000 lines per square centimetre, and that for street railway generators and motors and wherever fluctuations in load are sudden and great, toothed armatures are a necessity to avoid sparking. Prof. Crocker submitted a new type of unipolar dynamo, and spoke strongly in favour of the practical advantages of the unipolar principle. Prof. Anthony showed that the arc light only possessed an advantage of 50 per cent. over incandescent lamps in some cases when a certain minimum of light at any point in the surface illuminated is required. The Paper of Mr. Griscom treated of a number of obscure points connected with storage batteries. He showed that the rates of discharge of the different plates of a cell varied constantly in relation to each other, and referred to the curious buckling of plates when one side was illuminated more strongly than the other. Several problems were left for solution, one of which is the cause of the spontaneous and violent discharge of positives which sometimes occurs. Prof. Jackson's Paper related to experiments which contradicted the common belief that alternate currents deteriorate commercial fuses. The Paper of Dr. Bell was a defence of induction motors, and claimed that the efficiency of such motors at other than normal speeds did not differ from that of series motors under the same conditions. He also referred to the remarkable regulation of these motors, and to the fact that their power factor varied but slightly, even with wide variations of load. Dr. Duncan read a Paper on two-phased motors, containing the result of the application of his simultaneous method of alternate current analysis to both the primary and secondary, or the field and armature. Mr. Steinmetz read a continuation of his Paper on hysteresis, in which it is shown that hysteresis and molecular magnetic friction are not identical, and that at present commercial iron can be procured in this country better from a hysteretic standpoint than any tested by Prof. Ewing. The Paper of Dr. Pupin was on the application of his method of resonance analysis to the form of alternating current waves, and contained the result of researches into the origin of harmonics, which was found to lie in the alternator. One result of his analysis was to prove what has sometimes been disputed—that the rotary field in two- and three-phased motors does not vary in intensity. What promised to be the most valuable and lively discussion of the session—on the last papers named above—with Drs. Duncan and Pupin, and Messrs. Kennelly, Steinmetz, and several other able disputants present as participants, was, unfortunately, nipped in the bud by the final adjournment—a result of placing the most important papers at the tail of the programme.

"Inductance" and "Reactance."—One of the most important actions of the Institute at its annual meeting was the adoption of definitions of "inductance" and "reactance," two terms that originated with Mr. Oliver Heaviside, whose definitions of them are those accepted. The former has been adopted

Digitized by Google

as a substitute for the inconvenient expression "co-efficient of induction," the co-efficients of self- and mutual-induction being thus expressed as self- and mutual-inductance. "Reactance" is defined as that quantity in a circuit traversed by a periodic current "whose square added to the square of the ohmic resistance gives the square of the apparent resistance or impedance," though the final definition of the term was deferred owing to the lack of time to enter thoroughly into the subject at Philadelphia. The term "inductance" was recommended for adoption by the Institute Committee of Units and Standards, of which Mr. A. E. Kennelly is chairman, and "reactance" was proposed by Mr. C. P. Steinmetz during the discussion on the former at the annual meeting.

CORRESPONDENCE.

ELECTRIC WAVES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of February 16th last you printed a letter of mine on Electric Waves, and in a short note you made a few remarks in reference to it. You say, "It is possible for steady states of electric or magnetic force to exist independently of each other, but it is not possible for an electric field, varying with time, to exist without giving rise to a magnetic field, and *vice versâ*." Now this was the most important point raised, and I wished to have the proof given. I presume that theory does not show us that electric and magnetic fields can exist independently. That they can has been proved experimentally. Indeed, theory would appear to be rather against the idea. What it does assert is, "that changes of dielectric polarisation in non-conductors produce the same electromagnetic forces as do the currents which are equivalents to them." The only experiment which, as far as I can ascertain, has been considered decisive, was made by Hertz.* His Paper is entitled, "On Electromagnetic Effects Produced by Electrical Disturbances in Insulators." In this Paper he describes a number of experiments made with his well-known electric vibrator and resonator. His object was to ascertain whether any effect was produced upon an oscillating field by the approach of solid or liquid dielectrics. For this purpose he used masses of asphalt, artificial pitch, paper, sandstone, sulphur, paraffin, and petroleum. All produced a decided effect upon the field. Two possible explanations of the results obtained, besides the one adopted, occurred to Hertz, but he dismissed them upon consideration. Now, it must be remembered that when this Paper was written, Hertz had not discovered that electric and magnetic waves are propagated with finite velocity through dielectrics, and that they may be polarised, refracted, and reflected. It did not, therefore, occur to him that the phenomena he was observing might possibly be due to the reflection of the waves by the dielectric masses. At any rate, if his conclusions are sound, it is strange that such an important Paper should not be quoted in support of Maxwell's theory. I do not remember to have seen the experiment mentioned in Thomson's "Recent Researches." He states the theory, but does not give proof. No doubt the theory may prove to be the true one. At any rate, it is a very beautiful conception of Maxwell's, and appeals powerfully to the mathematical mind; but we must not forget, as Kelvin points out, that Descartes's doctrine of *vortices* died hard among the old mathematicians, and that although in the past they have done great things for electric science, they must not be allowed to weave the theoretical net so closely that new ideas cannot penetrate it.—Yours, &c.,

R. M. DEELEY.

Pressure on a Lamp Globe.—Those who have not made the calculations for themselves, says the *Electrical World*, may be surprised to know that the pressure of the air on the outside of the bulb of a 2,000 c.p. incandescent lamp having a surface of 300 square inches, is about $1\frac{3}{4}$ tons. No wonder they pop when they break.

* "Electric Waves," p. 95.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Caledonian Railway Company invite tenders for the supply of a quantity of various stores for twelve months from August 1st next. A complete list of the Company's requirements will be found set out in our advertisement columns. Specifications and forms of tender may be obtained from Mr. Jas. Lorimer, superintendent of stores; and patterns may be inspected at the Company's stores, St. Rollox. Tenders must be lodged with Mr. J. Blackburn, Secretary, at the Company's offices, 302, Buchanan-street, Glasgow, not later than Monday, June 18th.

———— The President and Governors of Robert Gordon's College, Aberdeen, are prepared to receive tenders for materials, motors, wiring, &c., for Robert Gordon's College and Gray's School of Art, Aberdeen. Further particulars are given in our advertisement columns, and tenders must be sent in, addressed to Mr. Thomas Fotheringham, Clerk of the College, by 12 noon on the 19th instant.

———— The Oswestry Electric Light and Power Company (Limited) invite tenders for engines, boilers, dynamos, cables, &c., for a central station at Oswestry. Tenders have to be in by June 16th.

———— The Guardians of the parish of Newcastle-upon-Tyne invite tenders for telephonic apparatus for communication with the workhouse. Tenders must be in by noon on the 22nd inst.

———— The Waterworks Committee of the Mansfield (Notts.) Corporation invite tenders for the erection of a line of poles and overhead wires for the automatic indicating apparatus and telephones between their Rainworth pumping station and the waterworks manager's office at the gas works, Mansfield. Tenders must be in by the 12th inst.

———— Messrs. Humphreys (Limited) require tenders for a private telephone installation to be fixed between their offices at Knightsbridge and the wharves at Ebury Bridge, W., and also between the offices and their iron building works, Hill-street, Knightsbridge.

———— The Urban Sanitary Authority of Bedford invite tenders for the building and chimney in connection with the proposed electricity works. Specifications, plans, &c., may be inspected at the offices of Mr. F. H. Medhurst, B.Sc., 13, Victoria-street, Westminster, London, S.W., or at the clerk's office, Town Hall, Bedford. Tenders have to be in by June 16th.

TENDERS ACCEPTED.—The tender of Messrs. Siemens Bros. and Co. for the supplying and laying of the cables necessary for the extension of the electric lighting area at Bolton, has been accepted.

———— The Electric Light Committee of the Dewsbury Board of Guardians have accepted the tender of their contractors to supply additional engines at a cost of £50 over the sum previously specified.

———— The Belfast Corporation have accepted the tender of Messrs. M'Laughlin and Harvey for the erection of the central electric lighting station in Chapel-lane, Belfast.

LIQUIDATIONS.—With reference to the Medical Battery Company (Limited), Mr. Justice Vaughan Williams has directed separate meetings of (1) the holders of debentures issued by the Company and the secured creditors of the Company, (2) the unsecured creditors of the Company, and (3) the contributories of the Company, to be held on June 15, 1894, at the Inns of Court Hotel, Lincoln's Inn, London.

———— Claims against the Electrical Engineering Company of Ireland (Limited) (in voluntary liquidation) must be sent in to Mr. J. M. Kean, 46 and 47, Dame-street, Dublin, by July 4th.

DISSOLUTION OF PARTNERSHIP.—The partnership existing between Mr. L. G. Tate and Mr. J. L. Fuller, trading under the name of Fuller and Tate, 20, Bucklersbury, E.C., will terminate on the 24th inst., after which date Mr. Fuller will carry on the business at the same address under the title of Fuller and Co.

PERSONAL.—Mr. Ernest Scott, A.I.E.E., who until recently was on the staff of the Brush Electrical Engineering Company, has been appointed chief of the drawing office department of the Electric Construction Company at Wolverhampton.

REMOVAL.—Messrs. A. Hurst and Co. have removed to Fenchurch-street-chambers, Church-row, Fenchurch-street, E.C.

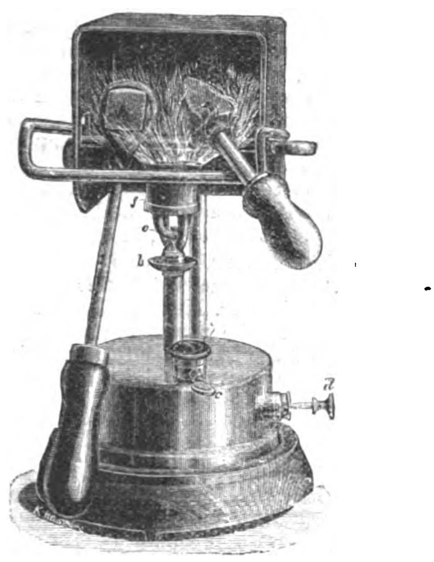
AGENCY.—Mr. W. T. Barnett, of 53, Victoria-street, S.W., has recently been appointed agent for the Southern District for Messrs. Mather and Coulson's manufactures.

MESSRS. BINKO AND CO.—This firm have purchased the goodwill and stock of the old established business of Messrs. Ridsdale and Co., of the Minories, lamp and lantern manufacturers, brass founders, fittings makers, &c., and have combined their new busi-

Digitized by Google

ness with that of the manufacture of electrical supplies carried on at Leadenhall-street. The name of Ridsdale and Co. is to be preserved and used in connection with supplies of nautical lamps, brass castings and specialities as hitherto. The two addresses of 34, Leadenhall-street and 54, Minories, E.C., will be retained.

Paraffin-Gas Apparatus.—A number of useful heating appliances, capable of burning ordinary paraffin oil without a wick, are supplied by Messrs. Moeller and Condrup, who are the London agents of the Swedish manufacturers. The accompanying illustration shows a heater for soldering irons; and another pattern



of heater, called the "Aetna" paraffin blow-lamp, ought to be serviceable to jointers, and for small welding and forging work. It is claimed that an intensely hot flame can be obtained by this apparatus, by means of which thick copper wire will melt in less than a minute; and that this result is attained at trifling cost, and without the use of pipes or chimneys.

The Universal Bell.—The International Electric Company, of Redcross-street, E.C., are issuing an illustrated circular giving particulars of the patent universal bell, which it is claimed can be used either as a slow-striking bell, as a single-stroke bell, or as an ordinary trembling bell. The bells are made with either 4, 5, or 6in. gongs.

Lamps for Tramcars.—Messrs. Ramsay and Co., of Glasgow, are engaged in making about 500 lamps of an improved pattern for use in the City Corporation's tramcars. The lamps are to be adapted for use either with the electric light, gas or oil, and are to be fitted with slides in various colours for use as head lights.

Pipe Tongs.—Mr. T. A. W. Clarke sends us a circular illustrating the patent pipe tongs manufactured at his Leicester works. These tongs are claimed to be an improvement upon the old parrot-nose tongs, while retaining all the merits of the old favourite. The tongs are so constructed that one pair will fit several sizes of pipes or sockets. There are six stock sizes of the tongs, and larger sizes are made to order.

Battersea (London).—A "looking-forward" motion that electric motors be substituted for horses in the vehicles belonging to the Battersea Vestry was discussed at the last meeting, and it was decided to refer the matter to the Electric Lighting Committee.

Baslow (Derbyshire).—The Local Board at their last meeting discussed a communication from Mr. E. Scott, Anderson, of Sheffield, informing the Board that the water-power available at Baslow was sufficient to provide motive-power for a public installation of electric light. The subject was adjourned for discussion by the incoming Local Board.

Batley Carr (Yorks.).—The extensive mill and works occupied by Messrs. Alfred Hill and Sons are being lighted throughout by electricity by Mr. A. Richmond Turner, of Dewsbury.

Belfast.—The Electric Lighting Committee's report states that it has been decided to charge 7d. per unit for electric current, with a meter rent varying from 2s. 6d. to 15s. per quarter, according to capacity, the rebates to be agreed to in conference with Prof. Kennedy. Enquiries have been received from intending consumers outside the area at present arranged for, and the Committee have decided to comply with the requirements, on condition that a "written undertaking is entered into for a minimum supply, for two years, of such an amount that the payment to be made shall not be less than 20 per cent. on the outlay of the Corporation in providing the necessary electric lines beyond 60ft. from the proposed distributing main."

Birkenhead.—On Wednesday the Finance Committee of the Corporation recommended that application be made to the Local Government Board for sanction to borrow £18,424 for the purpose of constructing a central electric lighting station at Bentinck-street.

Blackburn.—In connection with the lighting of the Free Library, concerning which two or three notes have appeared in our recent issues, we are asked to state that Mr. McLellan's contract is to supply and fix the lamps, pendants, and brackets.

Blackpool.—In answer to numerous complaints of the taking up of the thoroughfares, it has been pointed out that the calculations made under the original scheme have been so considerably upset by the increased demand, that it has been necessary to extend the original scheme, and to make provision for a much increased output to what had been originally estimated.

Bolton.—It has been decided to extend the electric lighting area to Newport-street, and an estimate presented by the Corporation's electrical engineer for carrying into effect a system of supplying electric fittings on the hire-purchase system has been adopted.

Bradford.—Messrs. Ullathorne and Hartley, have secured the contract for lighting the Theatre Royal and Opera House, Bradford, for which about 500 incandescents will be required. Another contract recently secured by this firm is for lighting the Self-Help Co-operative Society with 20 arcs and about 150 incandescents, the plant including a 12-h.p. Tangye gas engine.——The laying of the three-wire mains, is now being actively carried out here, and in connection with the extensions for which applications have been made to the Electric Supply Committee of the Corporation, a circular has been issued explaining the advantages of the electric light, and inquiring as to the amount of support likely to be given if the extensions are carried out.

Bristol.—The contract for lighting Bristol University College by electricity, has been given to Messrs. F. W. Ball and Co. About 200 incandescents will be required.

Chelmsford.—The Essex Standing Joint Committee has decided to light the County Room at the Shire Hall by electricity. Messrs. Crompton and Co. have obtained the order, the inclusive sum being £98. 10s.

Church and Chapel Lighting.—The Elm Grove Chapel, Portsmouth, is now lighted electrically.——The authorities at St. Jude's Church, Portsmouth, are considering the question of adopting the electric light.——The parish church, Leeds, is to be lighted with the electric light, the contract being in the hands of Messrs. Laing, Wharton, and Down, who are carrying out the work under the supervision of Messrs. Shepherd and Watney. The total cost will be about £500.——The church of St. Bride's, Kelvinside (Glasgow), has just been lighted electrically by the Kelvinside Electricity Company. The fittings are of ecclesiastical pattern in wrought iron and copper, and have a very harmonious effect with the surroundings. Several other churches in the Kelvinside district are considering the question of adopting the electric light.——Holy Trinity Church, Hull, is to be lighted by electricity, the authorities being at present in negotiation with several local electric light contractors in regard to the work.——Rudstone Church, a few miles from Bridlington Quay, is now lighted by electricity, the same motive power being used to blow the organ.

City of London.—It has been decided by the Library Committee of the Corporation to light a portion of the Records Chamber by electricity.

The Derby.—The Direct United Cable Company were successful in cabling and delivering to the news agencies in New York the result of the Derby, run on Wednesday last, at 10h. 22min. 15sec., or almost simultaneously with the time the news was received in London.

Dundee.—The Dundee Gas Commissioners will shortly be face to face with the necessity of considerably extending their electric lighting system. The capabilities of the present station are exhausted, and, while during the summer season there is sufficient capacity in the existing station, future requirements will necessitate considerable extensions, to which immediate attention must be given.

Electric Current for Organ Blowing.—A correspondent to the *Musical News* calls attention to the facilities offered by the London electric supply companies to supply current for organ blowing, and points out numerous advantages to be gained both by private and public organ owners.

Electric Light Arrears.—At the Mansion House, London, last week, the first summons for the non-payment of an account for the supply of electric current and rental of meter was heard. It was a summons against the United States Land and Investment Company for the sum of £5. 9s. 7d. Mr. G. Kebble, who appeared for the City of London Electric Lighting Company, asked that the Judge's Order be made to cover solicitor's costs, as there would be considerable difficulties in the event of non-payment by persons to whom the electric current had been supplied. The Magistrate agreed with this view, and made an order for the amount claimed and £1. 1s. costs.

Digitized by Google

Electric Organs.—The inauguration of an electric organ at Balruddery, near Dundee, is announced for to-morrow (Saturday), and it is said that Mr. J. More Smieton, the composer, has stated that the combination of the Thynne orchestral voicing with the Hope-Jones electric system has made this organ one of the finest instruments in the country.

Glasgow.—In reference to the proposed extension of the electric lighting system to the western district of the City, the subject has been postponed until the Electric Lighting Committee have ascertained from the annual financial statement the average cost to the Corporation of supplying each of the arc lamps at present in use for street lighting.

Greenock.—On Tuesday an ineffectual attempt was made to substitute electricity for the gas lighting of the Town Hall, and it was ultimately decided to introduce special gas fittings and reflectors. It was pointed out that the Gas Trust was already £5,000 in debt, and that, therefore, it would be unwise to introduce the electric light. Fears were entertained by several of the members that if the electric light were introduced, the revenues of the Gas Trust would be seriously weakened. Gas lighting was successful by ten votes to eight.

Hotel Lighting.—Messrs. Rashleigh Phipps and Co. have secured the contract for lighting the Norfolk Hotel, Surrey-street, London, W.C., with 425 16-c.p. lamps. The contract is to be completed in four weeks.

Huntly.—Mr. Stephen, of Bogieside, has under consideration a scheme for supplying the electric light to this district, for which, it is stated, he has plenty of spare power.

Ipswich.—The Electric Lighting Committee of the Town Council have selected Prof. A. B. W. Kennedy as consulting engineer for their electric lighting scheme, for which a Provisional Order is to be applied for in the coming session.

Londonderry.—At the last meeting of the Electric Lighting Committee of the Corporation the members were asked to take over the plant at the generating station. Mr. Blake, the Corporation's electrical engineer, submitted a final report, in which he stated that the tests he had made of the work done under the specifications by Messrs. Siemens Bros. and Co., Messrs. Alex. Brown and Sons, and Mr. M. M'Clelland had proved to his entire satisfaction; and he therefore asked them to take over the plant and buildings. A lengthy discussion ensued, and ultimately the report was adopted and the machinery taken over.

Mill Lighting.—Messrs. Berry and Pope have received instructions for installing the electric light at the mills of Messrs. R. Thompson and Sons, Padiham. About 270 incandescents are required. The firm have several other large installations in hand in the Burnley district.——The extensive corn mills occupied by Messrs. Fletcher, at Milford and Pentrich, near Belper, are now being installed with the electric light. These mills have been running night and day for a considerable time, and the electric light has become a necessity.

Miners' Lamps.—At the Woodyett Pit, Denny, where a fatal explosion took place last year, the miners now use electric lamps, which are stated to give every satisfaction.

Montrose.—The Kinnaber Waterworks have been successfully lighted throughout by electricity. The current was turned on on Thursday last week by the Provost, in the presence of the leading citizens. The Provost, in the course of his remarks, stated that though the present installation was small, they need not despair of seeing the whole of the town, including the private dwellings, lighted by electricity at no distant date. The motive power is obtained from a 12in. Pelton wheel attached to the supply main from the pumps to the reservoir, this providing a 125ft. head, so that only a small quantity of water is required.

Newcastle-on-Tyne.—It appears that the cost of lighting the city by gas is between £13,000 and £14,000 per annum, and, as stated in our last issue, a Committee has reported to the Corporation that it is advisable to take into consideration the question of lighting the city by electricity under the Corporation's control. The Corporation already possess a considerable amount of waste steam power at the refuse destructor works, Byker, where it is estimated power sufficient light to nearly the whole of the east end of the town is already at the Corporation's disposal.

Provisional Orders.—Notwithstanding that the application of the Wakefield Corporation for a Provisional Order under the Electrical Lighting Acts was presented later than the time allowed by the Standing Orders, a Committee of the House of Lords, after hearing the explanation of the agents for the promotors, decided to dispense with the Standing Orders.——The Monmouth Electric Lighting Provisional Order on Tuesday passed the House of Commons Committee on Unopposed Bills, and was reported for hird reading.——The Bill confirming the Provisional Order applied for authorising the Leyton Local Board to light their district by electricity, has passed the Standing Orders Committee of the House of Commons.——The Guildford Provisional Order has passed a Committee of the House of Lords, and has been read a second time.

Restaurant Lighting.—Many of the principal restaurants and cafés in the City of London have now adopted the electric light, to the very considerable benefit of employés and customers. The advantage of the light is particularly noticeable in the many underground and semi-underground coffee-rooms springing up in all parts of the city. The old gas-lighting arrangements rendered these coffee-rooms altogether unbearable, and must have militated considerably against their success from a commercial point of view. Many of these rooms, now that the electric light is introduced, are well patronised, and what must have proved a very up-hill work seems likely to result in considerable profit to the proprietors. There is scarcely a thoroughfare of any importance in the E.C. district without one or more of these basement cafés, which are likely to become, now that the electric light is an assured success, more than ever numerous and profitable. The money saved in redecorations alone must represent, in each case, a large sum.

Shirley and Freemantle.—In this district the provisions of the recently-passed Parish Councils Act were discussed at a recent public meeting, at which Mr. Killby, Chairman of the Local Board of Health, explained to the ratepayers present the nature of the powers and duties of the Parish and District Councils under the Act. He said that amongst the chief matters for discussion by the new Parish and District Councils would be the question of public lighting by electricity or other means. At Okehampton the introduction of electric lighting had, he said, led practically to the closing of the gas works. He did not think that the district he represented would be so cruel as this, but, doubtless, a considerable change in the method of lighting would shortly be brought about.

Shoreditch (London).—It would appear that the question of electric lighting in this district has not yet succeeded in overcoming the opposition of a considerable section of the members of the Vestry. A long discussion took place at the last meeting, but nothing definite was decided upon. An alternative plan to the Pitfield-street scheme has been brought forward, several of the members preferring a site adjoining the Vestry's wharf at Kingsland-road, N.

Stafford.—At the meeting of the Town Council on Tuesday the report of the Electric Lighting Committee was presented, and Mr. W. H. Peach called attention to some remarks made at the meeting of the Birmingham City Council in connection with the gas works. Mr. Peach noticed that there had been in Birmingham a large decrease in the manufacture of gas, which the Chairman of the Gas Committee there said was mainly due to the use of electricity. The Corporation of Birmingham had not the supply of electricity in their own hands, and were beginning to feel the competition of the electric light by the depreciation of their gas property. He mentioned this in order to show the wisdom of the Stafford Council in retaining in their own hands the monopoly of the lighting of the borough.

St. Annes-on-Sea.—A proposal for applying for a Provisional Order to light by electricity this district is under the consideration of the Local Board.

The Welsh National Eisteddfod.—Mr. W. H. Preece, who will deliver the inaugural address to the Cymmrodorion section, has selected for his subject "The Development of Welsh Industrial Resources."

Trade Conferences.—The series of trade conferences recently announced in connection with the Technical Education Board of the London County Council will commence on June 7th, when the building and furniture particulars will be read; on June 20th the engineering, shipbuilding, and metal trades.

Ventilation of Underground Railways.—In the House of Commons, on Monday, Mr. Weir asked the newly appointed President of the Board of Trade whether the subject of the ventilation of the Metropolitan Railway between certain specified stations had come under the consideration of the Board of Trade, and, if so, what steps had been taken in the matter. The reply of Mr. Bryce not being considered satisfactory, Mr. Weir wished to know whether electric traction might not be introduced, with the result that the stifling atmosphere now complained of would be abolished. Mr. Bryce: "Everybody knows that if electric traction were introduced the nuisance would be avoided."

Worthing.—In connection with the Electric Lighting Provisional Order which has passed a Committee of the House of Commons, a discussion took place at the last meeting of the Town Council, and it was decided not to circularise the district for support to the scheme; but the Chairman of the Electric Lighting Committee has been instructed to obtain expert opinion as to the cost of works and machinery.

Cricket.—The employés of the Westminster Electric Supply Corporation (Limited), have formed a cricket club, and will for the season play on the Raynes Park ground, Surrey.

Digitized by Google

WREXHAM.—The Wrexham Electric Lighting Company have authorised their solicitors to accept £350 from the Town Council for their rights in the electric lighting undertaking. This offer has been accepted by the Council on the understanding that if any insuperable difficulty should be found to prevent the carrying through of the arrangement, owing to the action of the Board of Trade, or otherwise, the Council reserve the privilege of withdrawing or cancelling the offer.

COMPANIES' MEETINGS AND REPORTS.

Gulcher (New) Electric Light and Power Company (Limited).

The sixth ordinary general meeting of this Company was held at Winchester House, E.C., on Monday last, Mr. D. de Castro presiding.

The SECRETARY (Mr. T. C. Morgan) read the notice convening the meeting, and the minutes of the two previous meetings, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said that the present meeting was preliminary to an extraordinary general meeting for winding-up the Company, and as they had only to criticise and pass the accounts, he thought that these could readily be disposed of. He would say a very few words on them, but at the same time he would be happy to explain to them the meaning of the net loss of £15,822, which he thought at first sight must have startled them all. He would refer immediately to the profit and loss account, because it would explain better than anything else the way in which this large apparent loss had been made up. The accounts came to hand at a very late date, but he would submit as concisely as he could the position of the affairs of the Company up to May 31st last, and he would ask them at the next meeting, if they decided to wind up voluntarily, to do so under a scheme which he would then have the pleasure of submitting. He did not know that he had any remarks to make on the balance-sheet, because he had no doubt they had all carefully studied it. Taking the manufacturing account, the stock on July 1, 1892, was entered in their books at £17,102. The plant that same year was valued at £6,732, so that really in the balance-sheet of 1892 the stock and plant together represented £23,835. They would see that the present valuation of these was set down at £12,500, or an apparent depreciation of £11,335. In other words, their late manager wrote off 50 per cent. from the stock and plant last year. The bad debts amounted to £1,421, of which £1,368 was contracted in 1891. There was also a small loss of about £70 over the general business. The preliminary expenses were put down at £1,200. They had been in the habit of writing off £400 a year from this item, but when they made up their minds that the Company ought to be liquidated, they thought it was only sensible to write off the whole of the preliminary expenses at once. All this amounted to £14,000, out of the net loss of £15,800, for the year that had passed, which, he hoped, would disabuse their minds of any idea that their business had not been properly conducted during that period. When they found, even after writing down these items in the way described, that there was the very considerable loss of £1,800, he thought it his duty to ascertain what would have been the loss in the ordinary course of business. They had written off between £3,000 and £4,000 a year from plant and stock, and £400 from preliminary expenses, allowing £100 at least for bad debts, so that they thought that their working loss would be £4,500—a constant quantity until the preliminary expenses had been abolished. Adding to this, £2,000, the difference between the figures he had given, it showed a loss on the year's trading of £6,408. Now, that was a loss made under almost every possible advantage of working except that of having plenty of capital. They had a very large and profitable order from New Zealand, and they thought at the last meeting that that order would pull the Company round. It had not done so, and he was now perfectly satisfied that with the present works, rent, and capital, the Gülcher Company could not possibly succeed, and therefore they had decided to move a resolution at the subsequent meeting for voluntarily winding it up. Having set out in detail the various sums making up the £15,832, he said that on the other side of the account he saw that the item by sales and hire of dynamos amounted to £24,368. He was sorry to say that of this amount very nearly £20,000, was due to the New Zealand contract. It was a very good contract and paid them well, but, as stated in the report, their sales in this country dwindled down to £5,000. This was the most serious matter which they had had to face, because it was quite clear that in electrical matters Providence was on the side of big armies. It was of no good for small companies to compete for central station work, and other work had practically fallen away. This was the most discouraging thing in the whole of their transactions. The consignment to the New Zealand branch was £1,814 for plant and stuff which they had sent out there for sale, there being no profit until it was sold there, and therefore it would come into the New Zealand account, and could not now be put down as sales. Stock in hand was written down very largely, namely, to £12,500. But their manager considered that a great deal of it was getting obsolete, and he would not certify that £12,500 was its value, and insisted on writing off 30 per cent. from it. He did exactly the same thing with the plant, on what principle he (the speaker) did not pretend to know, not being an engineer. At all events, the stock and plant were written down by one-third, which accounted for the apparent calamitous trading during last year. As was stated in the report, they had been contracting the business of the Company for the last four or five months. As soon as they saw and made up their minds that it should be wound up, they limited their undertakings. They borrowed £10,000 last August, they borrowed £5,000 on the debentures which were authorised to be issued, and £5,000 from their bankers, charging the second debenture-holders with it. The Directors—or some of them—had advanced to the Company since he saw them, to pay off the civil contract debts of the Company, £5,800, and the arrears of rent and taxes, amounting up to the end of June to £400. There were only 13 unsecured creditors remaining, the debts amounting to £100 each, or £1,300. The total debts of the Company were £20,825, exclusive of its shares. The assets were put down at £12,500; they had cash debts amounting to £4,900, and they had uncalled capital and calls in arrear £5,600, so that what he might call the assets treated as cash amounted to £23,000, as against £21,500 debts, showing an apparent surplus of £1,500. They had rather over 21,000 shares in the New Zealand Electrical Syndicate. As Directors they had tried to pay off everybody, and to distribute among the shareholders as many as possible of those 21,000 odd shares in the syndicate alluded to. If the scheme which he proposed were carried out, he hoped that there would be a substantial distribution of their property. Remembering the interest which they had in the New Zealand Syndicate he ought to tell them that he had made arrangements for the sale of the stock and plant—the assets of the Company—for £12,500, to be taken as follows:—£5,700 in cash, and £6,800 in shares of one of the large companies out there. He had all the contracts arranged with the assistance of Major Cotton, Mr. Grewing, and Mr. Meyerstein, so that they would be able to treat the £8,000 First Debentures as absolutely discharged. Then nothing remained to be dealt with but the bank loan of £5,000 and the £6,000 or thereabouts due to themselves. They thought, rightly or wrongly, that the Directors of a limited company ought to pay its creditors up to the hilt, just as much as if they were engaged in private trading, and they had decided to pay everyone in full. He hoped that their proposals would meet with the approval of the shareholders. He had seen almost every one of them, and they seemed not only to be willing but glad to consent to this arrangement. He concluded by moving the adoption of the report and accounts

Mr. LAMONT seconded the motion.

Major COTTON said that the report and balance-sheet fully proved what he had said for the last few years, that it would have been very much better for the shareholders if they had wound up instead of carrying on the business of the Company at such a heavy loss. He objected to the election of Mr. Rooper and of Captain Levett to seats at the Board, with which their connection had not been an advantage to the shareholders. He protested at the time against their taking those 20,000 shares in the New Zealand Syndicate, which he regarded as merely so much paper for their valuable stock, because he would be very much surprised if ever they got anything out of them.

The CHAIRMAN replied that both the Directors referred to by Major Cotton had been of great service to him personally, particularly the former on account of his technical knowledge; and he must remind Major Cotton that no man more persistently urged the desirability of having technical ability on the Board than Major Cotton himself. For the moment he would say nothing about the accounts, and would put the motion to the meeting, which he declared carried with three dissentients.

An extraordinary general meeting was afterwards held for the purpose of passing a special resolution requiring the Company to be wound up voluntarily, and for the appointment of a liquidator.

The SECRETARY having read the notice calling it,

The CHAIRMAN said that he proposed that the winding-up of the Company should be voluntary, but personally he would like it to be carried out under the supervision of the Court, notwithstanding that several shareholders and unsecured creditors seemed to hold the opinion that it would be a waste of the assets to go into Court. He was quite willing to waive his desire for a liquidation under the Court in deference to the wishes of those gentlemen, but at any rate, it was, he thought, desirable, having regard to the state of the accounts and the impossibility of carrying on the business that the Company should be wound up voluntarily, and that a liquidator should be appointed. He supposed that he ought, as the conduct of the business had been very much impugned by Major Cotton, especially in reference to the New Zealand contract, to refer to the position of affairs out there. It had been discussed *ad nauseam* for the last four or five years. Ever since 1888, when the contract was entered into, the history of the Company had been nothing more nor less than a struggle to get over the disastrous state of affairs brought about in that year. They were committed to a contract which they had estimated would cost £2,500 or £3,500, but which before its completion had run them in for £16,000. This fact accounted for the whole of their difficulties for that period.

Digitized by Google

He might, however, say that the Company was in a good financial position at the end of December, 1890, and but for what occurred in 1891 they ought to be in a good position now. He went away in 1890 to remedy the confusion into which their New Zealand affairs had fallen, and during his absence their manager, through his over-abundant energy or his desire to surprise him (the speaker) on his return with the work accomplished, incurred heavy losses. In all about £20,000 was considered to be sunk in that way, otherwise their accounts did not show badly for the rest of the time, even if they were not quite satisfactory. He then went on to explain the circumstances under which succeeding managers were appointed, to whom he said no one could attach any blame for the hapless plight into which the Company had got, pointing out that the fault was due to the position, size, and origination of the Company. The origin of the concern he characterised as the biggest swindle perpetrated in 1882, an allegation which he had never hesitated to repeat over and over again. No one knew better than Major Cotton that for the five years during which that gentleman had sat on the Board they were struggling to get rid of that original fraud. They had five bills to file in Chancery at once, and the result was that they succeeded in reconstructing the Company. Owing to the incompletion of a large contract, it was impossible to wind up the Company four years ago, as Major Cotton said they should have done. As to the New Zealand Syndicate shares, there was now no market for them; but, in his opinion, they would become a valuable property if they were able to maintain their position in the Colony in the way he thought they would be able to do. The stock which they possessed in New Zealand was practically unsaleable, and they thought that the best thing they could do was to exchange it for the said paper in a going concern, which might yet be very valuable. Having quoted a number of figures to show the progressive development of the property, he concluded by saying that it was merely a question of sitting tight on the saddle and riding well, and they would find that their shares would pay in the long run.

Major COTTON said that they had received a loan of £20,000 from the Gas and Water Trust, which might demand the money back at a certain date, when they would have to hand over everything—lock, stock, and barrel—at a great sacrifice in satisfaction of the claim of that Trust. He represented a large number of debentures, and he was not prepared to take shares in another company—he wanted cash.

The CHAIRMAN said that when he borrowed that £20,000 there was an income from it of £1,600 a year. It now yielded a return, he believed of nearly £5,000. Having regard to the circumstances under which the money was borrowed, he had no doubt that in the end of the year 1895 he would be able to make even better terms in the open market if the Gas and Water Trust were not disposed to renew the loan. He wished to rectify a mistake which he had made. He had stated that the debenture-holders would be paid off: £3,000 of the First Debentures would still remain. He was not prepared for Major Cotton's coming there to say that he was not prepared to take anything but cash for his interest. He thought that the arrangement was a binding one on everybody. That was the opinion of Mr. Grewing, from whom he had a letter stating that not only Major Cotton, but Mr. Meyerstein, and one or two other debenture holders, were prepared to take £5,000 in cash, and the rest in Second Debentures in another company.

Mr. LAMONT asked whether the liquidator would make a call.

The CHAIRMAN presumed that he would, and added, that after meeting the liabilities of the Company there might be some few pounds over for distribution among the shareholders. Very much would depend upon whether they would be forced into compulsory or voluntary liquidation. In further reply to Mr. Lamont, he said that arrangements had been made by himself for the proper control of their property in New Zealand. He understood that the First Debenture holders had agreed to take five-eighths of their holding in cash and three-eighths in Second Debentures of the large company out there. If that were not the case let them say so, and the concern must fall into immediate liquidation.

Mr. MEYERSTEIN said that at the meeting of the committee of debenture-holders various suggestions were made verbally, but as no decision had been come to in writing, he thought that that proposal had fallen through.

The CHAIRMAN, who said he had been ill since April, demurred, and said that it could have only fallen through during his illness. He did not know of it. He had a letter from Mr. Grewing saying that it was accepted, and he (the Chairman) had got the money to pay them off if the proposed resolution was passed at the confirmatory meeting to be held not later than a fortnight from that time. He quite agreed that there never was anything in black and white, but the matter was clearly understood. It went so far as this, that he had a circular printed and sent to the debenture holders on the subject, and he received from them proxies authorising him to act on their behalf, which he did. Of course, he could not enter into any binding contract without their consent; but all the preliminaries for a binding contract subject to their approval were completed, and he was asking their consent that day to let it be entered into, and five minutes after the next meeting confirming the resolution he would be able to hand them £3,000 in debentures and £5,000 in cash. He moved:—

"*That as from the accounts of the Company it appears that the Company cannot continue to carry on its business by reason of its liabilities, the Company be wound up voluntarily.*"

They thought it better to put the resolution in the form in which he moved it to give the shareholders an opportunity to consider the question, and to disapprove of it if they liked at the confirmatory meeting.

Mr. ADDISON seconded the motion, which was declared carried.

The CHAIRMAN next moved the appointment of Mr. C. F. Kemp, of Messrs. Kemp, Ford and Co., the auditor, as liquidator, which, after some opposition from Major Cotton and Mr. Meyerstein, was agreed to.

A vote of thanks to the Chairman, proposed by Mr. Lamont, terminated the proceedings.

Compagnie Française du Telegraphe de Paris à New York.

The following is an abstract of the report presented by the Directors to the general meeting held on the 31st ult:—

The Board of Directors appointed by the shareholders at the general meeting on May 25, 1893, in presenting their report and the balance-sheets A, B, C, D and E attached thereto, would point out that the first of these (A) was prepared from the books on February 28, 1893, by M. Lougarre, when he took charge of the Company as provisional administrator. The second statement (B) is the balance-sheet prepared from the books without alteration except the addition to the preceding balance-sheet (A) of the result of the working for the seven months during which the present Board of Directors had charge of the Company after M. Lougarre was relieved of his duties. The third statement (C) shows the position of the Company's affairs on December 31, 1893, and is the balance-sheet we now submit for your adoption. This balance-sheet shows no alteration in the amount of the capital of the Company, which remains at 42,000,000fr. Passing over several of the intermediate items, we come to, on the debtor side, the "Legal reserve" of 863,257fr. 14c., which we have been unable to find either securities or cash to meet, the securities which were supposed to represent this item having been appropriated for the necessities of the Company in 1887, 1888, and 1889. Another item in statement B, "Indemnity Submarine Company, 131,768fr. 75c.," does not represent an indemnity proper, but the repurchase of the cable connecting our Brest station with Penzance, which was laid by your Company at its own cost in 1880 under the condition that, although its use was reserved for this Company's benefit, it should become the property of the Submarine Telegraph Company, which at that time had the exclusive privilege of submarine telegraphic communication between France and England. This monopoly cased in 1889, and your Company repurchased the cable for £11,883, borrowed by annuities which have since been paid off. The necessary funds for this purpose were borrowed at 6 per cent. The item in statement B, "Redemption" 195,079fr. 65c., is also not covered by any cash or securities, and does not appear to be in conformity with No. 54 of our Articles of Association. We propose, therefore, to omit from the debit the items "Legal Reserve" and "Redemption," and from the credit the "Maintenance of Cables" and "Indemnity Submarine Company." The items "Cash at Paris and the stations," and "Cash at bankers," representing a total of 428,184fr., has been duly verified.

During the year we sold our property at Brest, for which we had no further use. It was valued on October 24, 1893, at 125,500fr., a figure which has not yet been realised. The item of 638,021fr. for "Cable in store" is cable valued at its purchase price. The large sum of 355,263fr. for material on board our cable ship, and at the stations has borne a depreciation of 5 per cent. off the figure given for December, 1892. "Cables and ship" stand in the balance-sheet at 33,907,973fr., and represent the same figure as in the accounts for 1892. Capital charges amounting to 6,358,077fr. also remain unchanged. We think it unnecessary to call attention at the moment to these latter amounts, which we think, however, will one day have to be considerably written down.

The "working" account for 1893 (during which we have had the management of the Company from June 1st to December 31st) shows a total gross traffic receipt of 2,348,639fr., out of which we have had to pay for "outpayments" and service 958,549fr., leaving net receipts 1,390,089fr., to which must be added the amount received from the chartering of the "Pouyer-Quertier" by the Société Française des Câbles sous-marins of 66,208fr., making a total gross receipt of 1,456,298fr. Deducting from this sum for general expenses 958,836fr., there remains a profit balance of 497,462fr., deducting which from the profit and loss account of 935,159fr., caused by the omission of the two items of "Legal reserve" and "Redemption," reduces this sum to 437,697fr. Other expenses of the year represent a total of 98,954fr., made up by "Repairs to land lines," "Damages paid for injury," "Fees and expenses paid to the provisional administrator," and "Compensation."

The report presented by the Provisional Administrator of the Company informs you of the breaking of the St. Pierre-Canso cable. This, however, was speedily repaired, and represents the only accident which occurred to our cables during 1893. On the return of the "Pouyer-Quertier" after her loan to the Société Française des Câbles sous-marins she was thoroughly overhauled; necessary repairs are now nearly completed, and we hope the vessel will be ready for service by the middle of June.

The five years' treaty entered into by this Company and the Commercial Cable Company in 1889 comes to an end on September 1st next.

Your Company acquired in February 5, 1892, a right to land cables on the Coast of Virginia, granted by the Senate of that State. Mr. Blaine, Under-Secretary of State of the Federal Government at that time, denied, however, the right of the Confederated States to grant concessions of that kind, and the question, although brought before Congress, has not been settled. The endeavour of M. Hector de Castro to settle this matter to the satisfaction of your Directors has not, up to the present, been successful, and an attempt by that gentleman to claim satisfaction from the Company before an American tribunal has been decided in our favour.

The action brought against this Company by the Anglo-American Telegraph Company, on account of the rupture of the common-purse agreements of 1880 and 1882, was called before the Court of Appeal in Paris at the beginning of May.

In November we entered into an agreement with M. Willot for a trial upon our cables of his relay, which had been already successfully applied on the lines and cables of the French Administration between Paris and Algiers. By this agreement we obtain, should success attend these experiments, all M. Willot's patents concerning submarine telegraph working, with the exception of the rights of the French Administration, and M. Willot enters our service for three years.

Digitized by Google

We have shown, gentlemen, that we have been able to arrive at a credit balance on the profit and loss account of 497,462fr. If we compare this result with that of 1892, which showed a loss of 22,829fr. 94c., or with that of 1891, which showed a balance of 46,053fr. 32c., it will be seen that our efforts have commenced to bear fruit.

In July, 1893, M. Noël Pardon, formerly Governor of New Caledonia, joined the Board, but vacated his seat in December on being reappointed to his old post by the French Government. The retiring Directors are MM. Boullaire, de Carrère, Chauvassaignes, and Laffargue, who are eligible for re-election.

At the general meeting the Directors' report, which was not sent out previously to the shareholders, but was handed to each person as he entered the room, was approved. Resolutions embodying the various suggestions of the Directors were carried unanimously; and the retiring Directors were re-elected.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

BAIRD, THOMPSON AND CO. (LIMITED).—This Company was registered, on June 5th, with a capital of £60,000, in £5 shares, to enter into an agreement made between John D. G. Thompson and Aubrey Richardson, for the sale to the Company of the business now carried on under the style of "Baird, Thompson and Co.," and to carry on the business of founders and workers of iron, brass and other metals, contractors for the ventilation and heating of buildings, &c., pneumatic and hydraulic engineers, electricians, electrical engineers, &c.

WILLIAM BARRACLOUGH (LIMITED).—This Company has been registered with a capital of £12,608, in £10 shares, to acquire the business of ironfounders, &c., now carried on by W. Barraclough at Stanningley, near Leeds.

CRUTO INCANDESCENT LAMP AGENCY (LIMITED).—This Company was registered on June 5th with a capital of £5,000 in £1 shares, to carry on, in the United Kingdom and elsewhere, the business of electric lighting in all its branches, and in particular to construct and fix all necessary cables, wires, lines, accumulators, lamps, and works, to generate, accumulate, distribute, and supply electricity to light cities, towns, streets, buildings, &c., and to carry on the business of electricians, electrical and mechanical engineers, &c.

ELECTROPHONE (LIMITED).—This Company was registered, on June 5th, with a capital of £20,000, in £5 shares, to acquire the undertaking of the Electrophone Syndicate, and all or any of the patent rights held by that Syndicate, and to manufacture and deal in telephones and all apparatus and appliances connected with the establishment or maintenance of telephonic communication.

TELPHER CABLE AND CLIFF RAILWAY SYNDICATE (LIMITED).—This Company has been registered with a capital of £6,000, in £10 shares, to acquire the concession granted to W. J. Brewer, C.E., authorising the construction of a cableway across the Dyke at Brighton and a cliff railway to Punch Bowl.

ROGER DAWSON (LIMITED).—The annual return of this Company, made up to May 14th, has been filed. The whole capital of £15,000 in £1 shares has been taken up, and of these 14,993 have been issued as fully paid, while the full amount has been called and paid on the seven signatories' shares.

T. L. HEMMING AND CO. (LIMITED).—The annual return of this Company, made up to April 2nd, was recently filed. Out of the nominal capital of £5,000 in £10 shares, all of which has been taken up, 130 have been issued as fully paid, while the full amounts have been called and paid on the remaining 370 shares.

HOOPER'S TELEGRAPH AND INDIA-RUBBER WORKS (LIMITED).—An agreement dated May 2nd, states that it is agreed that the business lately carried on at Millwall by William Hooper shall be sold to the Company (not, however, including the cash at the bankers or at the works or book debts), for £10,000, payable by the allotment as fully paid of 1,000 Preference shares, Nos. 1 to 1,000 inclusive, to William E. L. Hooper, Alice L. R. Hooper, John P. Hooper, Emily J. Moran, Mary E. A. Hooper, Samuel F. Hooper, Annie C. Marsh, Claude A. Hooper, and Anne M. Hooper. The contracts handed over to the Company include one for the custody and maintenance in sound electrical condition of 13 miles of 4½-ton cable belonging to the Great Northern Telegraph Company, for the custody of 20 miles of deep sea cable belonging to the Cuba Submarine Company (Limited), and running contracts with the General Electric Company. Messrs. John P. Hooper and Basil Gee become Directors and joint managers of the Company for seven years at a remuneration of £500 each per annum, and one-half of the profits remaining, after the payment of 5 per cent. per annum on the Ordinary shares, after making provision for a reserve fund.

JOHANNESBURG LIGHTING COMPANY (LIMITED).—The annual return of this Company made up to May 21st has been filed. The nominal capital is £150,000, divided into 50,000 Preference and 100,000 Ordinary shares of £1 each. All the Preference and 77,132 Ordinary shares have been taken up, and with the exception of seven Ordinary shares, have all been issued as fully paid. Upon these seven shares the full amount has been called and paid.

THOMPSON, RITCHIE AND CO. (LIMITED).—The annual return of this Company made up to May 21st has been filed. Out of a nominal capital of £5,000, divided into 200 Preference and 300 Ordinary shares of £10 each, 200 Preference and 140 Ordinary have been taken up and all issued as fully paid.

CITY NOTES.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended June 3rd were £869, as against £914 in the corresponding period of 1893, being a decrease of £45. The total receipts for the half-year amount to £20,012, as against £19,493 for the corresponding period of 1893, an increase of £519. The shares of this Company continue to show an upward tendency, the 4 per cent. debenture stock having had a sharp rise during the week.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of May are £3,550, as compared with £3,712 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—This Company's estimated traffic receipts for the month of May amounted to £1,594, as against £1,866 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of May amounted to £54,846, against £57,946 in the corresponding period of last year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of May amounted to £43,960, and to £45,395 in the corresponding period of 1893.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—The Directors of this Company have decided to recommend the payment of a further dividend upon the Ordinary shares at the rate of 40 per cent. per annum. for the six months ended May 31st last (making with the interim dividend of 10 per cent. already paid, 25 per cent. for the year), and a dividend on the Founders' shares of £30 per share for the year. The transfer books of the Company will be closed from the 12th to the 26th inst. inclusive.

GEORGE ANGUS AND COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend on the Ordinary shares at the rate of 5 per cent. per annum, payable July 1st.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for May, 1894, amount to £22,800, and from January 1st to May 31, 1894, £105,800. In the corresponding months of 1892 and 1893 the amounts were £104,800 and £108,000 respectively.

THE GULCHER COMPANY.—It will be seen from a report of the meeting of the shareholders of the Gulcher Electric Light and Power Company, appearing in this issue, that the Chairman intimated that a scheme had been prepared by the Board of Directors, under which the Debenture holders (for £8,000) would receive £5,000 in cash, and £3,000 in second Debentures of one of the leading electric manufacturing companies. The Chairman likewise said that it would be unlikely that the holders of Deferred shares would receive anything in the distribution of the assets of the Company which is shortly to take place.

SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The report of the Directors on the accounts for the year 1893 states that the balance of profit for the year is £585. 5s. 6½d., which the Directors propose to carry forward to the current year. In order to provide capital for the extension of mains into new districts and to defray the cost of new buildings, works, and machinery, which the development of the business and the increasing demand for current renders necessary, the Board recently resolved upon an issue of £25,000 Four and a-Half per Cent. Debentures and 6,000 Ordinary shares, and they are glad to report that this issue has been favourably received. Owing to the growth of the Company's business, and its probable development in the future, the Directors propose to submit to the shareholders at a meeting which will be called within the next few weeks an alteration in the Company's Memorandum and Articles of Association, with a view to making them more convenient and better adapted to the present status and requirements of the Company.

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—An extraordinary general meeting of the Swan United Electric Light Company (Limited) will be held at the Cannon-street Hotel, E.C., on Thursday, the 14th inst., at 12 o'clock, to consider and, if approved, to pass the following resolution, which, if passed by the required majority, will be submitted to a second meeting to be hereafter convened for confirmation as a special resolution, viz.:—"That the Swan United Electric Light Company (Limited) be wound up voluntarily, and that Henry Charles Gover, of No. 100, Victoria Street, in the City of Westminster, be, and he is hereby appointed, liquidator for the purpose of such winding up, and that the liquidator be, and he is hereby authorised to carry into effect upon the terms of a Provisional Agreement between the two Companies dated June 5th (subject to any modification), a sale of the Company's undertaking to the Edison and Swan United Electric Light Company (Limited) for debenture stock of that Company to be distributed among the members of this Company."

TELEGRAPH MANUFACTURING COMPANY (LIMITED).—The annual ordinary meeting of the shareholders of this Company was held at Helsby on Monday last, when a dividend of 5 per cent. and a bonus of 2½ per cent. were declared, being the same distribution as for last year.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended June 1st (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,637.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 839.—Vol. XXXIII. FRIDAY, JUNE 15, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The exhibits at the Royal Society Conversazione on Wednesday were, as a rule, repetitions of those shown in May. Perhaps the most interesting novelty was the Postmaster-General's exhibit, consisting of a Hughes' telegraph and a Wheatstone transmitter, each driven by a little Willmot air-motor. In the case of the Hughes instrument, the use of this motor enables a 132lb. weight and winding gear, and nearly all the train of wheel-work to be dispensed with. In the case of the Wheatstone, a 42lb. weight, which required rewinding every few seconds, is got rid of with its attendant complicated train of wheel-work. The speed of the motor is regulated by expanding or contracting the blast nozzle. The power required is so minute that a fair speed is attained by merely blowing into the motor supply tube with the mouth.

Dr. Oliver Lodge showed several forms of sensitive Hertzian wave detectors, the delicate susceptibilities of which were not a little upset by Prof. Thompson's three-phase experiments in the adjoining room. Mr. J. W. Swan exhibited several specimens of electro-deposited gold leaf four-millionths of an inch thick. The gold is deposited on a thin highly polished electro-deposited copper sheet, which is then dissolved off by perchloride of iron.

An attempt was made by Prof. Vernon Boys on Friday evening last to supply some of that impressiveness of style, which, though of small moment compared with a good popular exposition, may, as we observed last week, be used with advantage in conveying to a Royal Institution audience the importance of some of the subjects of the Friday evening discourses. Few other lecturers would have so scornfully rejected the title, "How to Weigh the Earth," and would have contented themselves with the colourless phrase, "The Newtonian Constant of Gravitation." The catch-penny title would, in a superficial way, have been the more impressive, gaining, indeed, by contrast with the delicate quartz-fibre refinements with which Prof. Boys has revolutionised many physical measurements. He contented himself with the difficult task of explaining what is meant by the constant of gravitation, and of showing its fundamental importance, while he repudiated any concern with the weight of the earth, as an accidental property of an insignificant planet, which might be dealt with by County Councils. The difficulty of the actual research was so great that the only chance of explaining it to the audience lay in the use of comparative figures. A model of Cavendish's apparatus was shown in which a force equal to the weight of $\frac{1}{3000}$th of a grain was measured. Prof. Boys, by deliberately choosing smaller dimensions, knowing that in his hands, at all events, greater accuracy would be obtained, limited himself to $\frac{1}{3000000}$th of a grain, and a torsion $\frac{1}{100000}$th of that of Cavendish. When his 16lb. lead balls were moved round his little golden pills they set up a whirlwind in his apparatus, at the raging speed of one inch in a fortnight, and making one revolution in six weeks.

Fearing a bad year, the Lockerbie Gas Commissioners recently sought to impose a gas contingent guarantee rate in order to pay therewith interest on capital and to meet the various liabilities of their undertaking. A local Hampden has, however, taken the matter into the Law Courts, and Lord Low in the Court of Session has decided against the Commissioners, and forbidden the imposition of the rate. If this decision were to be upheld, and if the law of electric were the same as the law of gas lighting, there would be joy amongst those who happen to have opposed the modern *penchant* for municipal electricity supply, and who foresee nothing but bad debts and corruption; at any rate, they, as innocent ratepayers, could not be made to suffer. Unfortunately all municipal Electric Lighting Provisional Orders contain the proviso that "any deficiency of income in any year shall be charged upon and payable out of the local rate."

The elaborate speculations which American electricians have been making during the past few weeks as to "the distance to which Niagara water-power can be economically transmitted by electricity"—when they have got it—strike one as being not a little premature. There is a ludicrous resemblance to betting on the future jumping performances of an unhatched frog. This is all the more the case, because it is by no means certain that, even in the event of the hatching being successful, there will be anyone anxious to have the creature jump very far, or to jump at all in their direction. One pair of mathematical speculators, arguing on certain convenient assumptions, arrived at the conclusion "that the power of Niagara Falls can be transmitted to a radius of 200 miles, cheaper than it can be produced at any point within that range by steam engines." Next comes a learned doctor who disputes the others' assumptions, invents his own, and concludes that the economical distance depends on several coefficients, but is never so great as 200 miles. Several other

Digitized by Google

writers take up the theme, arriving at various conclusions. Looking at the matter from a common-sense point of view, it would appear that to expect to arrive at any general formula for the radius of economical transmission, is simply ridiculous. The special requirements of the consumer, the character of the route, the ever-changing question of prices, all these affect the details of the problem in a way which must hopelessly baffle any useful general investigation.

The satirist who once declared that the American method of rating arc lamps consisted in taking photometer readings from each of the cardinal points of the compass, adding the quantities together, and calling the sum the candle-power, could scarcely have supposed that in the fulness of time a real American "electrical expert" would adopt this self-same method of specifying the candle-power of a lamp. Yet, it is the unexpected which happens. According to one of our American electrical contemporaries, the Board of Public Works of a city not so very distant from New York recently applied for expert advice relative to a clause in a street lighting contract with a local electric light company, and the following is the manner in which it was enlightened:—"The arc lights are hung at the street intersections, and each one throws its light in four directions; 2,000 c.p. of lights on each of the four streets cannot, therefore, be expected. An arc light which throws 500 c.p. of light along each of four streets is a 2,000-c.p. lamp, as called for in the contract."

Alloys.—Prof. Roberts-Austen has been awarded a prize of £80 by the Société d'Encouragement, for his researches on alloys.

Telephonic Communication in Sweden.—During last year the Swedish Government spent a sum of £55,500 in improving the telephone system of the country.

Académie des Sciences.—M. d'Arsonval has been elected to fill the vacancy in the ranks of the Académie des Sciences caused by the death of M. Brown-Séquard. The nomination requires the approbation of the President of the Republic.

Copper.—The copper output of the United States for the year 1893, amounted to 144,000 English tons, or only 1 per cent. less than in 1892, the average value of the copper at the place of production being £48 per ton, against £50 for 1892.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Accra-Kotonou	Apr. 1, 1894	June 14, 1894.
Bissao-Bolama	Nov. 24, 1893	—
Brest-St. Pierre (P.Q. Co.)	Mar. 29, 1894	—
Tarifa-Tangier	June 12, 1894	—

A New Arc-Lamp Carbon-Producing Process.—The firm of Krupp, of Essen, Germany, is reported to have introduced a new process for the production of carbons for arc lamps, by which it is claimed carbons having a life of from 17 to 28 per cent. longer than ordinary carbons are produced.

Aluminium.—The Société Electro-Metallurgique Française recently held its annual meeting, when it was stated that 500 kilogrammes of aluminium per day were being produced at the Proz Works, near Modane. It is intended to increase the production shortly so as to utilise the whole of the water-power available, estimated at 3,000 H.P.

Multiple-Filament Lamps.—Experiments with multiple-filament lamps having proved that there is practically no after-glow when the current is switched off, as in the case of single filament lamps, the Admiralty have directed that the multiple-filament lamp is to be adopted for mast-head flashing lanterns in all ships from second-class cruisers upwards.

International Congress of Hygiene and Demography.—A British Committee, of which Sir Douglas Galton is the Chairman, has been formed to further the interests in this country of the Eighth International Congress of Hygiene and Demography, which is to be held in Budapest, from September 1st to 8th this year. Any information may be obtained about the Congress from the Hon. Secretary, Dr. Paul F. Moline, 42, Walton-street, Chelsea, S.W.

Telegraphic Communication in Australia.—Some dissatisfaction exists in South Australia with the charges made for intercolonial telegrams, which are said to be higher in that colony than in the other colonies of the Australian continent. The Adelaide Chamber of Commerce is, therefore, taking steps to endeavour to bring about a uniform rate between the colonies of 1s. per ten words, and is inviting the assistance of other Chambers of Commerce.

Kew Observatory.—The Kew Observatory affords an excellent example of what may be done towards making a purely scientific institution more or less self-supporting, if only it is permitted to alloy the purity of its science with the baser metal of a little work of immediate practical utility. The outgoings at Kew amounted last year to £3,000, in round figures; grants from the Royal and Meteorological Societies amounted to nearly £900; but no less than £1,865. 3s. 3d. was derived from fees for various tests.

Exports of Telegraphic Wire and Apparatus.—The returns regarding the value of the telegraphic wire and apparatus connected therewith exported from this country during last month, although not showing the same activity as existed in 1892, must still be considered satisfactory, amounting as they do to £90,077 for the month, as against only £15,487 in May, 1893. During the past five months of this year the value of such exports is put down at £542,095, those for the corresponding periods of 1893 and 1892 being £450,921 and £651,658 respectively.

An International Institute of Engineers.—Since the inauguration and successful establishment and conduct of the World's Fair, the country, says the *Engineering Magazine*, instinctively looks to Chicago for the inception of grand ideas. It is therefore, perhaps, not surprising that from the Western Society of Engineers should come a suggestion for the formation of an International Institute of Engineers. It is eminently fitting, says our contemporary, that such a proposition should have originated with a man of international reputation like Mr. E. L. Corthell.

Non-Magnetic Watches.—In the report of the Kew Committee for 1893 it is stated that twelve watches, designated as "non-magnetic," were examined during the year, both as to their ordinary time-keeping and also as to their non-magnetic properties, and although the trial to which they were submitted was severe—the movement being tested in an intense magnetic field, both in vertical and horizontal positions, and gradually approached to and removed from the poles, whilst its behaviour was critically watched—in the majority of cases the watches were found to perform very satisfactorily.

Fareham.—Matters do not appear to be in a very prosperous state with the Fareham Electric Lighting Company. The concern has had a brief career of about four years, and now seems likely to collapse. The immediate cause of the trouble is the compulsion the Company is under to put its mains underground, together with the fact that the scant public support and recognition it is receiving will not justify the expenditure of capital necessary for this change. A short time ago the Company threatened the Local Board that it would abandon its Provisional Order. As the Local Board does not seem to be distressed at the threat, it is pretty certain the Company will have to abandon the Order.

Board of Trade Rules and Regulations.—The daily press has been circulating a paragraph to the effect that Mr. Francis Hopwood, Assistant-Secretary to the Board of Trade, has issued a circular letter notifying that the electric light regulations, dated July 6, 1891, are revoked, and promulgating new regulations and conditions for the safety of the public, and for ensuring a proper and sufficient supply of energy. Our readers

Digitized by Google

will be relieved to hear that the only foundation for this alarming rumour of the issue of yet another batch of rules, regulations, and restrictions is the application of the old rules to the undertakers of a certain Provisional Order.

Royal Society Government Grant.—In the account of the appropriation of the sum of £4,000 annually voted by Parliament to the Royal Society, to be employed in aiding the advancement of science, the following amounts were allotted to electrical researches from April 1, 1893, to March 31, 1894:—W. G. Rhodes, for a Minute Study of the Electrical Temperature Coefficient of some Pure Metals, with the view of obtaining an Electrical Thermometer more reliable than the Platinum Thermometer, £35; Dr. Schuster, for Assistance in certain Numerical Calculations concerning Terrestrial Magnetism, £50; W. A. Shenstone, for Continuing the Investigation of the Influence of Silent Discharge of Electricity on Oxygen and other Gases, £30.

Blackburn.—On Friday last Mr. Arnold Taylor, an inspector of the Local Government Board, held an inquiry with reference to the application of the Corporation for power to borrow money for the purposes of electric lighting. The Town Clerk traced the history of the electric lighting scheme, and said that in the early part of last year the Corporation made application to the Local Government Board for sanction to borrow £50,000 for the purpose of electric lighting, and in April sanction was granted. Owing, however, to a change in the site of the proposed electric light works, the sanction for £50,000 was cancelled. They now proposed to borrow £34,000 to cover the expenditure on plant. The inspector pointed out that the Corporation had allowed too large a sum for contingencies, whereupon the Town Clerk asked for sanction to borrow £32,000. The inquiry then terminated.

Electrical Communication with Lighthouses and Lightships.—In answer to a question in the House of Commons last week, Mr. Bryce said that in the last financial year £10,000 was placed at the disposal of the Board of Trade for the purpose of effecting electrical communication with light vessels, &c. That money was expended in connecting the Kentish Knock and Goodwin (N. Sand Head) light vessels and the Gunfleet Pile lighthouse with the shore. In the present financial year £11,000 had been similarly placed at the disposal of the Board of Trade, and it was intended to expend that amount in connecting the Haisborough and the Shipwash light vessels with the shore, and in laying a cable to the Tuskar Rock lighthouse. He was afraid that the other works recommended by the Royal Commission must wait until the Treasury could place more money at his disposal.

Search Lights and Torpedo Boats.—A test of the value of search lights for naval purposes was lately made at the naval station, Newport, R.I. It was arranged that during the evening of May 15th the torpedo boats "Cushing" and "Stiletto" should endeavour to enter the harbour while search lights should be employed in detecting them. The "Cushing" was painted nearly a black, while the "Stiletto" was left a dark green. The test took place at 9:30 in the evening. The boats entered the range of the search light and passed to their anchorage while the officers were still looking for them at the entrance to the bay. For ten minutes the boats were in the open channel, but the deep colour of the vessels blended with the colour of the rocky shores, so they were not detected. The German Government have decided to paint their torpedo-boats bluish-grey, this colour being, they consider, that least visible under the electric light.

Science and Engineering at Cambridge.—The University is at the present time crippled for want of funds. The wants of the University which are at the present time much pressing are—(1) The extension of the Cavendish Laboratory of Experimental Physics; (2) The commencement of the Geological Museum in honour of the late Prof. Sedgwick, towards which object a large sum has been already raised by subscription, but more is needed before the erection of the building can be proceeded with; (3) The Engineering School lately built with funds raised by the efforts of Prof. Ewing is still in need of much apparatus to give it requisite efficiency. The borrowing powers of the University are well-nigh exhausted, and it would not be prudent, in view of the falling off in the annual income of the common University fund, further to increase existing loans. In these circumstances it is hoped that, as in the past, some benefactors may be found to enable the University without delay to supply the three urgent works above specified.

Technical Training Conference.—There was a large attendance on Thursday night last at the offices of the London County Council, upon the occasion of the first of a series of trade conferences which have been arranged to discuss technical education in its relation to the various London industries. The meeting on Thursday night was confined to those interested in the building and furniture trades, and the chair was taken by Mr. Sidney Webb, Chairman of the Technical Education Board. Sir John Hutton offered the delegates a cordial welcome, and remarked that the members of the Board found that a mass of extremely useful teaching was given, but it was not made full use of because its existence was not largely known and there was a lack of funds. Several of the delegates then expressed their opinions with reference to different branches of the trade which they represented, and the subjects discussed included a suggested return to the old system of apprenticeship, with State protection for the men who had fulfilled its conditions; the modification of the practice by which apprentices were confined to one particular branch of their trade; the management of classes by men possessing practical knowledge; and the provision of additional half-holidays on which apprentices could receive instruction in technical matters and other subjects. The conference unanimously adopted a resolution in favour of greater facilities being extended to apprentices for attending technical classes by means of at least one half-holiday a week. Matters of detail were then discussed.

Electric Phenomena during Thunderstorms.—Mr. C. S. Du Riche Preller has contributed a letter to the *Standard*, in which he gives a graphic description of some electric phenomena during thunderstorms which have come under his personal notice. The following extract may interest our readers:—

"The large 'village' of Gossau, about seven miles from the town of St. Gall, derives its electric supply for lighting and motive power for industrial purposes from a hydro-electrical central station, situated at a distance of eight miles, by a high-tension transmission, with transformer stations in the village. The thunderstorm, accompanied by violent lightning discharges, passed over the place at five p.m., and then, driven back by a change of wind, returned and lasted for several hours. Soon after five p.m. all the electric lights went out spontaneously, but the place was illuminated by violent sparks and flashes, which were emitted by the overhead wire system, and ran along the conductors. These phenomena reached their height at the principal transformer station, close to an hotel; for here the high-pressure current escaped from the conductors to the earth, viz., the ground saturated with rain, the effect being a succession of flashes or continuous blaze, which so endangered the building that the Fire Brigade had to be called out to protect it. These phenomena continued for several hours, till the electric supply was cut off at the central station, a special messenger on horseback having been despatched thither, for, wonderful to relate, the installation was as yet without telephonic communication. Only last summer I witnessed a similar occurrence on the Mont Salève electric railway, near Geneva, where the lightning struck the feed-conductor of the line, and thence found its way along the transmission cables to the central station, fully two miles distant, where it passed through the lightning arrester and burnt out one of the huge 1,000-H.P. dynamos. In this case, too, the lightning discharge was only the indirect cause, the direct cause being that the dynamo was running at the time—viz., that the current followed the discharge through the not quite perfect lightning arrester, and 'short-circuited' the dynamo."

The Restoration of the Apparently Electrocuted.—The formula for restoring the vitality of the apparently drowned is nowadays well known. Briefly, its main object is to induce the lungs to recommence their normal respiratory functions. According to M. d'Arsonval, precisely similar treatment should be tried on the apparently electrocuted. A few weeks ago MM. Picou and Maurice Leblanc were afforded an opportunity of putting M. d'Arsonval's prescription to the test at the St. Denis generating station. At the time of the accident an electrometer showed that a difference of potential of 4,500 volts existed between two of the three wires of the transmission line, the frequency being 55. The three wires are carried by insulators supported by a bracket fixed into the wall of the station some 20ft. above the floor. A man engaged in putting up a telephone wire was seated astride a bracket below, holding on to one wire with his hand. At that moment the telephone wire, one end of which was in contact with the bracket on which the man was seated, came in contact with

Digitized by Google

another of the three wires. How long the man was actually short circuiting the 4,500 volts it is impossible to say. Some minutes, however, certainly elapsed before the current was cut off, and a quarter of an hour after the man was still sitting senseless on the bracket, and it was another half hour before he could be got down. Artificial respiration was immediately tried, and in two hours time the man could talk, and is now none the worse for his experience, with the exception of a few burns.

Obituary.—The death is announced of Prof. August Kundt, who died at Israelsdorf, near Übeck, on the 21st ult. Prof. Kundt was born in Mecklenburg on November 18, 1839. He received his scientific education in Berlin, and from 1866 onwards filled in rapid succession the chair of Professor of Physics at Zürich, Würzburg, and Strasburg. In 1888 Prof. Kundt succeeded von Helmholtz in the management of the Physikalisches Institut, in Berlin. Prof. Kundt was one of the old school of natural philosophers, who took an active and productive interest in everything connected with physics. In every branch of physical science he has published valuable memoirs; optics, acoustics, electricity, and magnetism have all been enriched by his labours. In acoustics he devoted himself to the study of the motion of solid and gaseous bodies, and to him is due the discovery of dust figures in closed pipes, by which simple means it is possible to measure the velocity of sound in gases, and to compare it with the velocity in solids. He investigated the behaviour of those bodies which, like rosaniline, produce an anomalous spectrum in which the red and orange rays are more refracted than the green and blue, thus changing the usual order of succession of the colours. In the course of his investigations on anomalous dispersion, he found that it was peculiar to those substances which exhibited a strong absorption for certain colours, a fact which theoretical considerations subsequently confirmed. Prof. Kundt also busied himself respecting the optical properties of thin films of the metals, and even succeeded in measuring the refractive index of some of them. In conjunction with Warburg, he did valuable work on the conduction of heat and the friction of gases; and, in conjunction with Röntgen, on the rotation of the plane of polarisation in gases.

The Manufacture of Engineers.—To the correspondence on this subject in the columns of the *Engineer*, to which we referred on p. 121 of our last issue, "A Young Engineer" from Glasgow contributes the following:—

SIR: Your correspondent "Pater" deserves the gratitude of all the young members of the profession for his praiseworthy attempt to dissuade young men from entering a profession which is already crowded to overflowing. His position as a practical engineer and the father of a family will no doubt give weight to his argument in the opinions of many of your non-technical readers, to whom, I take it, the warning is specially directed. While cordially endorsing all that he says as a practical engineer, I wish to point out that, by his own statements, he has gone beyond the sphere of his experience in attacking technical colleges as the source of the evil above referred to. It is a common occurrence in our day to see men build up fantastic theories for the purpose of demolishing them, and I venture to suggest that your worthy correspondent lays himself open to this charge. He clearly has no knowledge of technical colleges, or he would not make the ludicrous mistake of assuming that professors of engineering go touting for pupils, and lead inexperienced parents to believe that when their sons have studied under them for three years they become qualified engineers. I am personally acquainted with most of the said professors in Great Britain, but I must confess that I know of none to whom your correspondent's argument applies. My experience of them is that they are honourable men in the highest sense of the word, and this is fully borne out by the kindly relations which generally exist between professors of engineering and their pupils in after life. Now, Sir, can anyone with an atom of common sense believe that this would be the case if your correspondent's theory was a true one! Your correspondent evidently forgets that a man may be a successful business man, and even possess an engineering works, without being an engineer in the true sense of the word. In conclusion, I may mention that I am one of the "bye products" of a technical college; but as I have earned a living as a journeyman mechanic, and as a draughtsman, I beg leave to subscribe myself—A YOUNG ENGINEER."

University College of South Wales.—An influential deputation representing the educational interests of South Wales and Monmouthshire waited, on Thursday last week, on the Master Wardens and Court of the Drapers' Company at Drapers' Hall, Throgmorton-street, for the purpose of explaining the present financial position of the University College of South Wales, to whose funds the Drapers' Company have liberally contributed, with the view of enlisting further assistance. Prof. V. Jones, Principal of the College, explained the object of the deputation, stating that it was to solicit a continuance of the kindness which the Drapers' Company had already from time to time extended to the South Wales University College. Five years ago the Company were good enough, in response to a petition, in the first place, to give the college £1,000 for the establishment of a scholarship. The second gift of the Company had assumed the form of a donation of £1,000 towards capital expenditure in respect of higher technical education in the college. Further, the Company had granted the college £300 per annum for five years towards the establishment of a professorship of mechanical engineering. The deputation desired to thank the Drapers' Company for the assistance it had rendered the college in the past, to ask for the continued support of the Company towards the maintenance of the professorship that bore the Company's name, and to point out that the large increase in the number of the departments in the college, as well as in the number of the students, had produced the result that the present buildings were inadequate to the amount of work required to be done. The Master (Sir. J. H. Johnson) expressed the pleasure it had given himself and and his colleagues to receive so influential a deputation, and said that the statements which had been presented would receive very favourable consideration.

Graphic Methods of Calculation.—The increasing popularity of graphical methods of calculation, as compared with the more precise (but not necessarily more accurate) analytical methods, suggests some thoughts which may not, says Mr. H. H. Suplee in the *Engineering Magazine*, be out of place, bearing as they do, upon problems directly relating to the daily work of the mechanical engineer. The great attraction of graphical methods, remarks Mr. Suplee, lies in the directness with which the result is attained and the fact that the whole work is before the observer in a shape to be grasped as a unit, instead of a succession of statements. Every one who has used tables and curve-diagrams to express the same set of relations—such, for instance, as a set of Regnault's steam tables compared with a curve of steam-pressures and volumes—will appreciate this fact. Even the simple exercise of graphical addition, marking off the successive items on a strip of paper and then measuring the total length, is in fact doing what is considered quite a feat by the expert arithmetician, as it permits items of several columns in width, as well as fractional quantities of all denominations, to be added simultaneously, without previous reduction. The clumsy notation of the ancient Greeks and Romans compelled them to direct their mathematical ingenuity almost entirely to the solution of geometrical problems, and any one who has seen even a simple example in elementary arithmetic worked out in the Roman system of numerals can imagine how the veriest schoolboy of to-day would appear as a mathematical prodigy, merely because of the fact that he possessed the infinitely superior notation possible with the Indian (miscalled Arabic) numerals. When we consider, however, how many unnecessary details of reduction and similar manipulation are avoided by the most elementary graphical processes, the reflection that we are entirely too well satisfied with our present system forces itself upon us. May it not be possible that as great an improvement upon the Indian system as that was over the Roman is possible, and that, while the solution by graphical methods is only an indication of what may be attainable, yet the indication may be clear and the solution not far off? There are some analogies in our present system which point in the same direction—notably the curious properties of the figures nine and seven; and the manner in which such arithmetical prodigies as Mondeux, Colburn, Bidder, and Inaudi operated, makes one regret that the processes by which they performed calculations mentally which required much longer time for "experts" to accomplish with pencil and paper, were not investigated, at least to an extent which would give a clue to the conscious or unconscious process employed. The direct methods of nature go immediately to the results which they must produce, just as a freely-suspended chain forms a catenary without requiring any guidance, and it may not be too much to hope that some day we shall be able to think and calculate by methods as direct as the action of the forces which we are endeavouring to grasp.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 100.)

Furnaces and Boilers.

Water Room.—Not only the rapidity of circulation, but several other important actions in a boiler are affected by the amount of water room provided, or rather by the ratio which this space bears to the heating surface and grate area. Where the amount of water in the boiler is large as compared with the surface which is provided for heating that water, it is evident that a longer time will be spent in raising steam than where there is a larger allowance of heating surface. There are indeed two reasons for this. The first is the obvious reason that where a given rate of heat supply has to heat a large mass of water it will take longer than where it has only to heat a small mass. The second reason is, that if attempts are made to rapidly heat a bulky boiler the stresses which will arise on account of unequal expansions will seriously injure the boiler and involve serious risks; while with a less bulky boiler the circulation being much more rapid, there is a greater tendency to equalisation of temperatures, and steam can be raised much more rapidly without risk of serious consequences. On the other hand the large mass of hot water in a boiler under steam serves a very useful purpose, as will presently be seen, in regulating the pressure of the steam. The following Table (XIII.) shows approximately the relation between the water room and heating surface in some important boilers:—

Table XIII.

Type of Boiler.	Ratio of Water Room in cubic ft. to Heating Surface in sq. ft.
Cornish	0·90 to 1·00
Lancashire	0·60 to 0·80
Galloway	0·50 to 0·60
Return Tube	0·40 to 0·45
Locomotive	0·12 to 0·20
Babcock-Wilcox Water Tube	0·14 to 0·15

Regulating Effect of Water Room.—Hot water in a boiler is a store of heat energy, which, by a perfectly automatic action, tends to minimise the fall of pressure whenever steam is drawn off through the steam pipe. To make the action clear, let us suppose that we have a Lancashire boiler, containing 25,000lb. of water at the temperature of the steam, the pressure of the steam being 100lb. on the gauge. We will, in the first place, assume that no heat is being supplied from the fire, and we will afterwards consider what will happen if heat is so supplied. Let us suppose that we wish to draw off steam without allowing the pressure to fall more than 5lb. How much steam can be drawn off? Neglecting the steam in the steam space, the whole of the steam drawn off will be produced by evaporation at the surface of the water. Directly any steam is drawn off, the pressure and temperature of the steam above the water will fall, but before it can fall perceptibly the water will commence to evaporate, and thus to make new steam, thereby tending to keep the pressure up. Steam at 100lb. pressure on the gauge has a temperature of 338°F., while steam at 5lb. lower pressure has a temperature of 334·6°F. The difference in temperature is 3·4°F. Consequently the 25,000lb. of hot water may go on making steam, by virtue of its stored heat, until it has fallen 3·4°F., without fear of the pressure dropping more than 5lb. This fall of temperature corresponds to a loss of 85,000 B.T.U. Now, the average latent heat of 1lb. of steam between 115lb. and 110lb. absolute pressure is equal to 794·7, which, if divided into 85,000, will give about 107lb. as the weight of steam which may be generated by this amount of heat. Here, then, the heat stored in the water compensates the draught of steam to the extent of 107lb. We will next suppose that the furnace is supplying heat and generating steam at a certain rate, say, W pounds per minute. Then, if a sudden increase in the demand for steam arises, the furnace may not be in a condition to meet it instantaneously. Suppose the demand rises to W + 10lb. of steam per minute, it is evident that the hot water will keep the steam pressure above 95lb. on the gauge for over ten minutes, and in this time it would be easy to get the fires into a more active state, or the extra demand for steam may have passed away.

Mr. Druitt Halpin has devised a system of thermal storage for the purpose of meeting the fluctuating demands for steam at an electric power station. In this system it is proposed to have a very large mass of hot water, contained under pressure in steel cylinders, available for evaporating in the manner already described; the steam thus generated by the hot water being used for helping the boilers over the heaviest loads. We may here observe that this proposed remedy for fluctuating loads is to be placed, not as near as possible to, but as far as possible away from the source of fluctuation, thereby causing the fluctuations to be imposed on a long series of intermediate parts, including the steam mains, engines, and gearing.

Evaporating Surface.—The allowance of surface of water from which to permit steam to be given off varies considerably with different types of boilers. Some makers have considered that a boiler should not be forced to give more steam than at the rate of about 25lb. or 30lb. per square foot of water surface per hour, while others have designed boilers to give steam at nearly five times this rate. With electric power boilers the limits of allowance may be represented, on the one hand, by the Lancashire boiler, and, on the other hand, by the boiler of Messrs. Babcock and Wilcox. In the Lancashire boiler, under ordinary rates of steaming, the evaporation is at the rate of from 25lb. to 35lb. of steam per square foot of water per hour; and with 50 per cent. forcing of the steaming rate this is not brought to more than from 38lb. to 53lb. per square foot per hour. The Babcock and Wilcox boiler, however, has an allowance of as much as 52lb. of steam per square foot of water per hour under normal steaming rate, with as much as 78lb. when the boiler is forced to steam 50 per cent. faster. Moreover, in the former boiler it is comparatively easy to maintain the full amount of evaporative surface, for the large water space will not permit the water level to fall very rapidly, while, if it does fall, there will not be any reduction but an increase of the width of the water surface. Whereas, in the latter boiler, the bulk of water is much smaller, and the curvature of the drum is much more rapid, so that it is more difficult to maintain the water line and to keep up the maximum evaporative surface.

The object in view in designing that a boiler shall not develop steam at too high a rate per square foot of water surface, is based upon the fact that excessively rapid evolution of steam from a water surface is liable to carry unevaporated masses of water over into the steam space, and possibly into the steam mains with the steam. This is known as *priming*; and the wetness of steam which follows upon priming in the boiler is, of course, injurious to the efficiency and proper working of the steam plant. This, among other reasons, is why it is impossible to get satisfactory results with a heavily forced boiler. Mr. Crompton claims* for the Babcock and Wilcox boiler, that it will stand 50 per cent. of forcing without producing wet steam; but it is evident that this could only be done under the most careful management, with a perfectly steady rate of steaming. A Lancashire boiler will stand, so far as the priming goes, far more forcing than this; but not with a high furnace efficiency, owing to the loss of heat up the chimney.

Steam Space.—In every boiler a certain amount of space is left for the accumulation of steam, between the evaporating surface and the top of the shell. The object in making this space large is to allow of the return of most of the primed water, before it can reach the steam pipe. In some types of boilers, mostly of older date, the distance traversed by the steam before it can reach the steam pipe is increased by the use of a steam dome, or small separate chamber fitted on to the top of the shell. As this dome weakened the shell it has largely

Digitized by Google

been abandoned. The regulating effect of steam space being very much lower than that of an equal volume of water space, makers of boilers have latterly sought to minimise the amount of steam space while preventing the priming of water into the steam pipes. This has been done by using baffle plates and perforated pipes for the collection of steam, as well as by the use of more direct forms of steam separators. Steam space, where the shell is a horizontal cylinder, becomes a necessity also on account of the necessity for a certain area of water surface; for if the water level is raised this surface becomes reduced. Table XIV. gives the usual allowances of steam space in some typical boilers.

Table XIV.

Feed Water.—The performance of a boiler is greatly affected by the quality of the feed water, and with the manner of feeding it. The sources of boiler water in electric-power stations are town mains, wells, and artesian borings, adjacent rivers, and in some rare cases canals. The nature of the source affects the character and amount of saline and mineral matter dissolved in the feed water, and as these are largely deposited in a solid form wherever the water is heated, it is very desirable to obtain a water as free as possible from either permanent or temporary hardness. The deposition of these solids on the useful heating surface will reduce the efficiency of the surface, and will expose the plates or tubes to risk of burning, owing to the much higher temperature to which they will be raised by the furnace gases. The frequent cleaning, often attended with considerable manual labour, which these deposits make it necessary for the boiler to have, will increase the cost of maintenance. If the water is fed cold into the boiler all the deposition and incrustation will occur in the boiler, while, if the water is raised nearly to the steaming temperature in a separate feed-heater, a considerable amount of the mineral matter will be deposited before the water enters the boiler, and it may be collected in suitable mud-drums.

Cold Feed.—It is only rarely that one hears of boilers being fed with water at its natural temperature in connection with electric-power stations, for the practice is almost intolerable. Cold feed, besides having the objectionable feature just named, causes the boiler-shell and internal flues to become locally cooled, resulting in unequal expansions and injurious strains. Further, by chilling the plates locally it tends to the deposition of a hard incrustation on the furnace side of the plates. Thus, both the life and the efficiency of the boiler are diminished. Besides these features, a boiler fed with cold water will not evaporate as great a weight of water per hour as one fed nearly at the steaming temperature, because the boiler has in the former case the additional duty of warming up the water. Now, it can be shown, as the result of experience in hundreds of factories, that a greater evaporation can be obtained, with a given amount of heating surface, if some of the heating surface only is placed in the boiler, the rest being placed in a separate feed-heater, called an economiser.

Hot Feed.—The reason for this is that it is difficult to build a boiler, on any of the usual lines, which will reduce the furnace gases down to about 300°F., without having a most bulky and inefficient boiler, while it is quite practicable to reduce the furnace gases to from 400° to 500°F. by a good boiler, and afterwards to take the surplus heat out of them by means of an economiser. It is, therefore, in the joint interest of the life, efficiency, and steaming capacity of a boiler, to feed it with hot water rather than with cold. The following are the methods of warming feed-water before injecting it into the boiler:—

(1). By means of an exhaust steam heater, *i.e.*, by passing the heat of the steam exhausted from the engines through metal partitions into the feed water.

(2). By taking the feed water from the condenser hot well, *i.e.*, utilising the condensed steam drawn from a surface condenser. This is simply an extension of (1).

(3). By taking the warm water, part of which is condensed exhaust steam, from a jet condenser.

(4). By admixture of live steam with the feed water.

(5). By taking some of the heat from the furnace gases after they leave the boiler flues, and passing this heat through metal partitions into the feed water.

"Compactum" Feed Water Heater.—It is obvious that the maximum temperature to which the feed water can be raised by exhaust steam is very much lower than the evaporating temperature in the boiler, being necessarily lower than the temperature of the exhaust steam. An exhaust steam feed-heater is a form of surface condenser, but with insufficient surface to condense more than a small proportion of the steam. It is therefore unprovided with special pumps, the condensed steam being trapped out of the steam space and the feed water being kept in circulation by the feed pump. A form of exhaust steam feed heater met with in some electric power stations is the "Compactum" heater, manufactured by Messrs. Kirkaldy, Limited, a vertical section of which is shown in Fig. 16. The exhaust connection with the engines is made

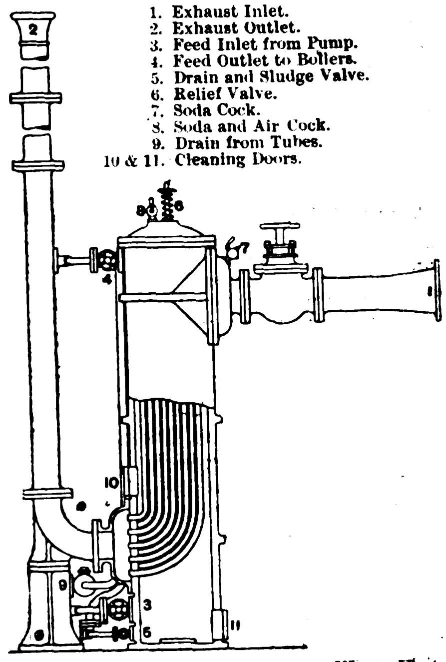

FIG. 16.—"Compactum" Exhaust Feed-Water Heater.

at 1, and the admission of the steam is regulated by the adjacent stop valve. The steam passes through this valve into a large number of parallel pipes of thin sheet brass, which terminate at each end in a small chamber; and from the chamber at the lower end, the cooled steam passes away to the exhaust up-take, 2, and the condensed water is drained through 9. The system of pipes is contained within a vertical cylinder, into the bottom of which, at 8, the feed water enters, and from the top of which, at 4, this water passes on to the boilers, being propelled through the apparatus by the ordinary pumps. It will be seen that the feed water has free circulation between the parallel steam pipes, enabling it to become considerably raised in temperature between the inlet and outlet points. The allowance of pipe surface in these feed-heaters varies from one to two square feet per 30lb. of feed water per hour. It is an economical practice to choose a feed-heater sufficiently large to enable the whole of the feed water to pass through it at a slow speed, as this enables the feed water to deposit its mineral matter in the heater, while, if the water passes rapidly through the heater, the mineral matter will largely be carried into the boiler. Anti-incrustation fluids should be injected into the feed-heater; never directly into the boiler.

NOTES ON ELECTROLYSIS.

BY JOHN WADDELL, D.SC. (EDIN.)

Introductory.

Before entering upon the particular subject of electrolysis, it will be well to consider the analogy between an electrical machine or galvanic battery and an air fan, an analogy which is becoming familiar in the consideration of motors, though not so widely applied as it might be.

Suppose an air-tight box, made similar to a ventilating shaft, but with its ends closed, and a fan revolving in it in the usual manner. In one end of the box air will be compressed, while in the other it will be rarefied. There is evidently a limit to the amount of compression and rarefaction for any fan, for it is impossible for all the air to be exhausted from one end, and, moreover, the compressed air tends to slip back past the fan. The difference of air pressure on the two sides of the fan depends upon its construction and upon the method of setting-up in the box, as well as upon its speed of rotation. The *size* of the box has little effect, except in influencing the time which is required for reaching the limit of difference of pressure. A small fan may be capable of producing greater difference of pressure than a large fan, and the difference of pressure does not depend upon the total quantity of air; for in a small box the difference of pressure between the two ends may be greater than in a large box, if the fan in the small box is more effective.

So far we have an analogy with a frictional electric machine or a Holtz machine (or, indeed, with a galvanic cell, with circuit unclosed), the difference of pressure of air representing difference of potential of the two terminals which is not affected by the size of the conductors, except that as the conductors have larger capacity longer time is necessary for the machine to reach the limit of its power to create difference of potential.

Electrical capacity is analagous to size of the box containing air just as difference of potential is analagous to difference of pressure.

Returing to the original illustration. If a small opening be made in each end of the box containing air, the fan will not be able to create such a difference of pressure as before, because air will flow in on one side and prevent so great rarefaction, and flow out on the other side and prevent so great compression. If the openings are enlarged there will be still less difference of pressure on the two sides of the fan. This represents the case of a Holtz machine connected with conductors having a smaller or larger number of points.

Suppose the two ends of the box to be joined up by pipe external to the fan chamber, so that air which is compressed on one side of the fan returns to the other side through the pipe there is a continual circulation of air, a continual current.

Suppose friction absent, then, if the fan has been moving long enough to make the current of air constant, since there is no acceleration of the mass of the air, there will be no work done by the fan; but, under such circumstances, the pressure on the two sides of the fan will be equalised, and the action would be precisely the same as if the fan after communicating the motion to the air were suddenly to vanish.

Owing to the friction of air, however, the pressure does, in practice, differ on the two sides of the fan, and the quantity of air which flows round the circuit in a minute depends upon the difference of pressure and upon the friction. So long as the quantity of air, passing per minute through the pipe is constant, all the work done by the fan is against friction and develops heat. The work done by the fan is exactly equivalent to the heat produced. Moreover, all other conditions remaining the same, the fan, by working harder would increase the difference of pressure, and, therefore, the quantity of air passing per minute, and therefore the friction, and therefore the heat. If, on the other hand, the passage of the air is made more difficult than to keep the same current going, the difference of pressure must be increased, and the heat produced by the friction is also increased. The work done by the passage of air, therefore, would in a given time be proportional to the difference of pressure and proportional to the quantity of air passing, except that the friction of air passing rapidly is greater in proportion than of air passing slowly.

In the case of an electrical circuit, there is no limitation such as has been just mentioned. The work done by a galvanic battery or a dynamo being proportional to the difference of potential created by it, and proportional to that factor ordinarily called *current of electricity*, a factor which is analogous to current of air. The unit of difference of potential being the *volt*, and the unit of current the *ampere*, the product gives the electrical unit of power which is called the *watt*, and is $\frac{1}{746}$ of a horse-power. (Power is work done in unit time.)

Electrolytic Phenomena and Analysis.

If a current passes through a metallic conductor, it produces a heating effect, and no other change. If it passes through such substances as fused salts or aqueous solutions of salts, acids or bases, the conductor is decomposed. This decomposition is called *electrolysis*, and the conductor which is decomposed is called an *electrolyte*. The products of decomposition are set free at the places where the current enters, and leaves the electrolyte at what are called the *electrodes*, which usually consist of metal or carbon plates or rods.

The electrodes are necessarily of different potential, else there would be no flow of electricity from one to the other; the electrode of higher potential is the *anode*, the other the *cathode*. The products of decomposition are usually denominated *ions*. Since bodies of high potential repell other bodies of high potential, and attract those of low potential, the ions separating at the anode are of lower potential than those separating at the cathode, or, as commonly stated, are *electro-negative*, the ions separating at the cathode being *electro-positive*.

If water is decomposed by a current, oxygen separates at the anode and hydrogen at the cathode, in equivalent amounts, eight parts by weight of oxygen to one of hydrogen, or one volume of oxygen to two of hydrogen. Not only is this so, but if a current be passed through a series of electrolytes, equivalent weights of the ions will separate at the electrodes in each electrolyte. This law of equivalents was stated by Faraday in 1833.

If, for example, a current be passed through the series of electrolytes, acidulated water, and aqueous solutions of silver nitrate, lead acetate and antimony trichloride, it will be found that at the cathodes hydrogen, silver, lead and antimony will be separated in the proportions by weight of $1:108:\frac{208}{2}:\frac{120}{3}$, equivalent ions being separated at the anodes. In all parts of an electric circuit the current is the same, therefore the amount of any of the ions separated corresponds to the quantity of electricity passing. The fact that, however the conditions may be varied, a current is always accompanied by an amount of decomposition proportional to the strength of current, seems to prove that there is no conductivity apart from the transport of the ions nothing which corresponds to metallic conductivity, but that the conductivity of an electrolyte is similar to the power of a fluid to carry heat by convection.

As, then, electricity is conveyed by the ions, it is not strange that equivalent weights carry equal quantities. Since one atom of silver or potassium is equivalent to one atom of hydrogen, it is evident that all three carry the same charge of electricity. The capacity of the three atoms is equal. On the other hand, one atom of lead being equivalent to two atoms of hydrogen, it must carry twice the electric charge, and in the same way the atom of antimony three times the charge carried by hydrogen. Copper, in the decomposition of *cupric* salts, carries twice the charge of copper in the *cuprous* salts, because, in the former case, it acts as a divalent element, in the latter as monovalent. In the case of potassium ferrocyanide, $K_4F_2Cy_6$, the ions are potassium and the radical F_2Cy_6, and the radical F_2Cy_6 carries four units of negative electricity (if the quantity of electricity carried by one atom of hydrogen be taken as the unit of positive electricity) because it is equivalent to four atoms of potassium. But in potassium ferricyanide, $K_3F_2Cy_6$, the radical F_2Cy_6 carries three units only of negative electricity.

The question may be asked, how is it that substances whose heat of combination vary so much should be decomposed by a current in exactly equivalent quantities? A little considera-

Digitized by Google

tion will elucidate the matter. Heat of combination is a form of energy, and quantity of electricity, which alone has been so far discussed, is not energy. It was stated above that the work done by a galvanic battery or a dynamo depends upon *the difference of potential* created by it, as well as upon the current which passes in the circuit. In the same way, the work done in the electrolyte depends, *not only upon the current, but also upon the difference of potential between the electrodes due to the separation of the different ions upon them.*

The analogy of the fan causing a current of air gives a useful illustration. The work of the fan need not all be expended against friction, but the air set in motion may be employed to drive machinery. A number of machines might be driven by the same current of air, each machine doing a different amount of work. The current of air could be produced by a powerful fan, and might be used for causing the rotation of a series of less powerful fans, employed to drive machinery of various kinds. When work is done by any of the fans there is a difference of pressure of air on each side of it, and if one fan does twice as much work as another, the difference of pressure in the former case is twice that in the latter, the quantity of air passing each fan in a given time being the same. This difference of pressure is quite independent of the friction of the air; in the circuit it is merely due to the difficulty of rotating the fan, which is the greater the greater the work it has to do.

In an electric circuit, the case is the same when motors are placed in series. Each motor employs the same current, but the different motors may do different amounts of work, owing to a varying difference of the potential of their terminals. To take a numerical example, if a dynamo is working with a difference of potential between its terminals of 1,000 volts, and if there are in the circuit three motors in series, and if there is a fall of potential, at the first motor of 100 volts, at the second of 200 volts, and at the third of 500 volts, the second and third motors do, respectively, two and five times as much work as the first, all necessarily using the same current because in the same circuit. Moreover, all the motors combined use $\frac{800}{1000}$ of the total work done in the circuit, the remainder heating the resistance.

In the same manner precisely, a current passing through three electrolytes may do different amounts of work in each, though the current is the same, owing to the varying difference of potential between the electrodes. The difference of potential between the terminals both in the case of motors and of electrolytes is called *counter electromotive* force.

The origin of the term is easily seen, for if the cycle of work were reversed, and the machinery instead of being *driven by* the armature were to *drive* the armature in a reverse direction, there would be a difference of potential between the terminals such as to cause a current of electricity opposite to that of the dynamo, hence the term *counter* electromotive force.

The case of the electrolyte is similar. In the above examples the fall of potential due to the resistance of the conductivity wires in the motor, or of the liquid in the electrolyte, has been left out of account just as in the case of the fans any difference of pressure of air owing to friction in passing the blades of the fan has been neglected. In practice this may not be negligible, and heat is produced in the conductors. The matter, so far as necessary for the present purpose, will be spoken of later.

If the armature of a motor be rotating very slowly it will produce very little counter electromotive force, but if it be allowed to rotate more rapidly the counter electromotive force will increase until, theoretically, it may equal that of the dynamo, the rotation being sufficiently rapid. In this case, there would be no current in the circuit, and therefore no work done by either dynamo or motor. In practice, it is, of course, impossible to completely attain the conditions just mentioned; but if there be very little load on the motor, its armature may rotate so fast as to permit very little current in the circuit.

A dynamo, or galvanic battery of very low electromotive force, could cause rotation of the armature of a motor, provided the work done by such rotation is less than that of the dynamo, and there is not too great loss of energy in the form of heat or otherwise. The counter electromotive force may have any value from zero to that of the generator. With a dynamo of large electromotive force the maximum limit of the counter electromotive force is raised, the minimum limit still being zero.

An electrolyte is different from a motor in this respect, that its counter electromotive force varies within narrow limits having a certain minimum as well as maximum value. A galvanic cell may not have a sufficiently high electromotive force to decompose the electrolyte at all, and therefore no current passes; not because the resistance of the electrolyte is so great, but because decomposition would produce a counter electromotive force greater than the electromotive force of the galvanic cell. In an actual experiment, roughly carried out in order to illustrate the principle, it was found that a Daniell cell joined with a resistance and a tangent galvanometer in circuit, caused a deflection of the needle in the latter of 7deg. A Grove cell under the same conditions gave a deflection of nearly 14deg. This latter cell in circuit with a water voltameter and the same galvanometer gave a reading on the latter of 6deg., while the Daniell cell under the same conditions produced no deflection of the needle. The reason was that the Grove cell has an electromotive force nearly double that of the Daniell, and the counter electromotive force of water decomposed between platinum electrodes is greater than that of the Daniell cell and less than that of the Grove. Two Daniell cells, in series, would have caused a current through the electrolyte. If there were a number of cells in series with the electrolyte they would cause more rapid decomposition; but there would be very little, if any, change in the counter electromotive force.

If the electrodes are plates of large size, and very close together, the resistance of the electrolyte is small; but if the electrodes are small, the resistance may be considerable. The resistance of the electrolyte causes a difference of potential between the electrodes, and in this respect is similar to counter electromotive force. On this account the ordinary Wheatstone bridge is not convenient for measuring the resistance of an electrolyte, but if the battery in the usual arrangement is replaced by a Ruhmkorff coil, the effect of the counter electromotive force is got rid of, because the current is alternating, and the electrode, which at one instant is anode, is at the next instant cathode, and there is no setting free of ions on the plates. Since the current is alternating, a galvanometer cannot be employed in the bridge, its place is taken by a telephone, which speaks if the resistances are not balanced, but is silent if they are. (Further details upon this matter are given in Oswald's "Outlines of General Chemistry," translated by Walker, page 279.)

The relationship between counter electromotive force, and the fall of potential in the electrolyte, due to its resistance, can be clearly seen by a numerical example. Suppose a battery to supply a current, at a pressure of eight volts, the resistance in the total circuit being 800 ohms, and the counter electromotive force of the electrolyte two volts; there will be an effective electromotive force of six volts, causing a current of $\frac{6}{800}$ amperes, through the resistance of 800 ohms.

Suppose the resistance of the electrolyte to be practically zero, then the difference of potential between the electrodes will be two volts. There will be decomposition of the electrolyte, corresponding to the current, and all the work done in the electrolyte will go to its decomposition. The current in the rest of the circuit, whose resistance is 800 ohms, will produce heat, the quantity of heat being by Joule's law proportional to $C^2 R$. If the conditions be now changed so that the electrolyte has 100 ohms resistance, the remaining 700 ohms being in other parts of the circuit; the difference of potential between the electrode will be increased. The counter electromotive force will be two volts as before, but there will be an additional $\frac{6}{8}$ volt, due to the resistance of the electrolyte, which is $\frac{1}{8}$ the total resistance. The effective electromotive force in the whole circuit being still six volts. The strength of current will not be changed, and therefore the rate of decomposition of the electrolyte will remain as before, but the electrolyte will become heated, the amount of heat developed in the electrolyte will be $\frac{1}{8}$ the total heat developed, because its resistance is $\frac{1}{8}$ the total resistance, but the total heat will be precisely what it was in the first instance.

Digitized by Google

If the battery should be changed, so as to give a pressure of 10 volts, the current would be increased, the effective electromotive force being now eight volts. The resistance remaining still 800 ohms, the current would be $\frac{8}{800}$ amperes, therefore a decomposition of the electrolyte would take place at a rate more rapid than before in the ratio of 8:6. With the resistance in electrolyte 100 ohms, heat would be developed, but this heat would not be $\frac{8}{6}$ of what it was before, but according to Joule's law above cited $(\frac{8}{6})^2$ its former value. It would remain still $\frac{1}{8}$ of the total heat developed in the circuit, the total being increased in the same ratio, a little consideration will show that the difference of potential between the electrode would be three volts, of which two are owing to the counter electromotive force.

Application of Principles to Battery.

The law of equivalents in electrolytes applies to the battery itself. For every 63·5 grammes of copper deposited from a solution of sulphate of copper electrolysed 65 grammes of zinc must be consumed in the battery; if a single cell only is employed, and if there is no local action in the cell. It is not an uncommon idea that this statement will hold only if no other work is done in the circuit, such as heating the circuit, that is, if there is no resistance, or, at all events, no resistance except in the electrolyte itself. The resistance in the circuit makes no difference in the ratio between the quantity of zinc used up in the single cell and the amount of the electrolyte decomposed.

This follows from the fact that electricity is conveyed only by the ions; hence the ions must travel in the galvanic cell just as in the electrolyte, and the travelling of the ions in the cell is possible only when zinc is consumed.

The resistance merely diminishes the quantity of electricty which will flow in a given time; the electrolyte will be decomposed more slowly; but, on the other hand, the zinc will be used up more slowly in the same proportion. It is entirely a matter of indifference, so far as the rate of decomposition of the electrolyte or the rate of consumption of zinc in the cell is concerned, *where* the resistance is, whether in the cell or in the connecting wires, or in the electrolyte. The *position* of greatest resistance determines merely the *position* of greatest development of heat. The energy which shows itself as heat is merely the difference between the energy developed by the galvanic cell in the chemical action going on there, and the energy used up by the electrolyte in its decomposition. The latter in some cases may be zero, as, for instance, when copper sulphate is electrolysed between copper electrodes. The energy used up by the decomposition of the copper sulphate is given out again by the re-formation of that salt; as the copper is deposited on the cathode it is taken from the anode. In such a case all the energy goes to heating the circuit. By lessening the resistance the action will go on faster, the current will be greater, and the heat develop more *rapidly*; but otherwise there will be no difference. The energy of the chemical action going on in the cell will produce its equivalent heat somewhere.

In the statement above, the galvanic battery has been assumed to consist of a single cell. If there are two or more cells in series in the battery, more zinc will on the whole be used than is equivalent to the electrolyte decomposed. In fact, each cell of the series will consume the equivalent zinc, since in each cell the current is carried by the ions.

Suppose, in illustration, that copper sulphate is the electrolyte and the electrodes copper, one Daniell cell will produce a certain current, C, depending on the resistance. There will be 65 grammes of zinc used up for 63·5 grammes of copper deposited on the cathode.

Now, suppose two Daniell cells placed in series, the resistance remaining the same as before, the electromotive force will be doubled, therefore the current will now be 2 C. This being so, twice the quantity of zinc will be used up in *each* Daniell as was consumed before; in all, therefore, four times as much zinc as before. But since the current is twice what it was, twice as much copper will be deposited on the cathode as before; so that, while the zinc consumed is increased four-fold, the copper deposited is increased only two-fold. There is therefore a loss of energy, the two extra equivalents of zinc being wasted as heat.

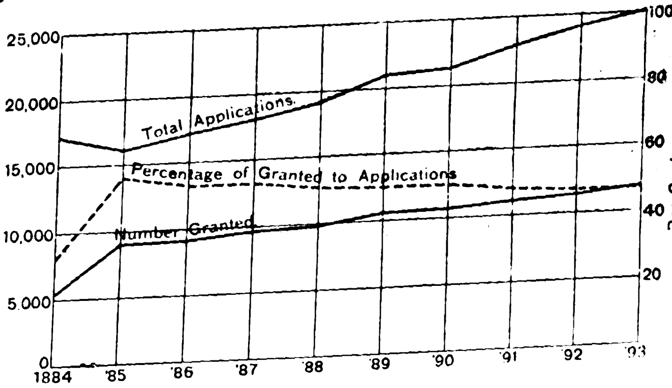
For electrolytic purposes, therefore, it is not economical to increase the electromotive force of a battery by putting on more cells in series; if rapid decomposition is required, the best way is to diminish the resistance in the circuit as much as possible. This statement raises no question except that of economical use of zinc in the battery, it has nothing to do with the matter of convenience of manipulation or excellence of the work performed.

That the two cells in series must consume four times as much zinc as a single cell with the resistance unchanged, is evident from another consideration; the electromotive force is doubled and the current doubled, therefore the power of the battery which is the product of the two, must be increased four-fold. The consumption of the zinc is the source of the power, and, therefore, it must also be increased four-fold.

By a similar argument, it can be shown that two similar dynamos in series will require four times as much power to drive them as either of them alone would require in order to keep up its electromotive force. It is left to the reader to follow out this point, and to trace, if he chooses, the analogy in the working of a series of fans.

PATENTS IN 1893.

During last year 25,120 patents were applied for, as against 24,169 in 1892, an increase of 4 per cent. The Comptroller-General in his report states that the practice of filing a complete specification at the time of application is growing in favour, and that every year the number of applications accompanied by provisional specifications which are allowed to lapse



through omission to file complete specifications becomes relatively larger. The names of eight gentlemen were added to the register of Patent Agents during the year, the total number upon the register upon December 31, 1893, amounting to 237.

The total income of the Patent Office in 1893 amounted to close on £175,000, against nearly £200,000 for 1892. The outgoings amounted to £95,000, leaving a handsome surplus of £80,000, or £23,000 less than last year.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

WEDNESDAY, June 20th.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Meeting at 20, Hanover-square.

ROYAL METEOROLOGICAL SOCIETY.

8 p.m. Ordinary Meeting at 25, Great George-street.

FRIDAY, June 22nd.

PHYSICAL SOCIETY.

5 p.m. (1) An Exhibition of Photographs of Flames, by Capt. Abney; (2) "An Elementary Theory of Planimeters," by Prof. Henrici; (3) "The Hatchet Planimeter," by F. W. Hill; (4) "A New Integrating Apparatus," by A. Sharp. Other Papers if time allows.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

(The Oldest Electrical Journal, 1861–1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :
1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.
Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
- VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
- VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d. post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free. Also in German, 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 8s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

LECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

In Preparation. Very fully illustrated.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. Being Four Lectures delivered in April-May, 1894, before the Royal Institution, by Prof. J. A. FLEMING, M.A., D.Sc., F.R.S.

NOW READY.

Volume XXXII. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad, carriage extra.

Cases for binding Volume XXXII., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

MUNICIPAL ELECTRICAL APPOINTMENTS.

Advertisements inviting applications for the position of "Electrician," "Resident Engineer," or "Manager" are now so frequently appearing that it may be of interest to give some attention to the probable position of a successful candidate. The large number of applications sent in for all vacant posts has caused an uneasy impression that the supply of competent engineers far exceeds the demand, and we fear this must always remain true until some standard qualifications in both mechanical engineering and electrical knowledge are generally recognised and defined; the unfortunate result at the present time being that the few qualified men suffer from the glut of embryo engineers who fire off applications regardless, and probably ignorant of, the deficiency of their training. The task of examining testimonials when solely committed to the care of a professional adviser is probably lightened by his skilful winnowing of talk from deeds; but if these applications, with their accompanying testimonials, are placed before the members of an average Corporation or Town Council the bewildering array of talent seeking their patronage must have a tendency to increase their pride in their importance and to depreciate the value of the services of the chosen man; in fact, they may justly say to him, "Engineers are cheap to-day, and if we don't like you there are plenty more." An obvious remedy for this plethora of inexperienced aspirants would be the publication of the minimum requisite qualifications, but this would practically mean a definition of the much-abused title, assumed at discretion by the plumber, bell-hanger, upholsterer, and others, who call themselves electrical engineers by virtue of handling wire and nails; and as such a definition has never yet been attempted, it is not surprising that statements or advertisements of municipal staff requirements are published in somewhat general terms, though occasionally one reads that the applicant must have had experience in a "central station" with, perhaps a modicum of "theoretical training," whatever that may mean. If, as we hope, the time has now arrived

Digitized by Google

when all agree that the work involved in reducing the potential energy in coal to the maximum amount of electrical energy, and utilising and supplying the same with the least waste, is simply and solely a mechanical operation, and therefore entirely within the province of a mechanical engineer conversant with electrical science, then the term "electrician" may revert to its original meaning, and to those experts in the cable-testing rooms who originally assumed it.

A mechanical engineer may have theoretical or practical, or perhaps both qualifications, but as his duty in an electricity supply works is to manage men and handle material, it follows that to be worthy of this position he must have had practical employment in the workshops, and if this has been accompanied by sound theoretical training, he is all the more likely to have realised the importance of his work. We confess it would be a relief to see future inquiries for electrical engineers accompanied by a proviso that the applicant must have had at least three years' shop practice and some experience in electricity supply works, any further qualifications being enumerated or implied in the statement of duties; these conditions would tend to stem the tide with its ever-increasing flow of unqualified applicants, and while many would retire from the field rather than face the difficulties before them, those who had the pluck and determination to place their ambition on firm ground would not only facilitate all their future labours, but would also improve their prospects and the position of their profession. This desirable result might be attained if consulting engineers would mutually draw up specifications for the most perfect resident engineer, &c., and agree amongst themselves that they will recommend only those applicants who fulfil the requirements. In many cases the consulting engineer is placed in a delicate position as regards the final selection, for though the municipal authority may consult him, it sometimes happens that they have a decided preference for a local aspirant who has neither sympathy with the consulting engineer, nor the necessary experience and knowledge to appreciate his labours; every hitch in the working of the plant or mains somehow becomes magnified into a great blunder which the municipal authority are led to believe can only be rectified by the local aspirant—in fact, the reputation of consulting engineer and contractors is at the mercy of the successful candidate who has slipped in through the wide meshes of a general statement of qualifications, which the consulting engineer has not elaborated into an acknowledged form of close specification. The remuneration now offered for appointments involving serious responsibility cannot be considered very generous, and consulting engineers might reasonably be expected to suggest a more liberal and adequate return for labours upon the success of which so much depends. A perusal of the statements of duties recently issued by various corporations and boroughs will give an impression that the candidate will find it all very easy if he only carries out the orders and instructions to be given him by others, and a feeling of curiosity may be pardoned if we wonder what these instructions are likely to be, for we find in one document of this kind some evidence that the selected "electrician," also referred to in the advertisement as an electrical engineer, is to be considered as a tame and helpless subordinate in the department of the borough surveyor. We read that the electrical engineer must attend to his duties at such hours as the borough engineer may direct, all reports being made to the latter, who is evidently the only authority to whom the successful electrician has access.

Many electrical engineers are at present so enamoured of municipalisation of electric supply, for the obvious reason that corporations and vestries have ready-money orders to give, that no general observations on the subject are likely to receive much attention, nor is the present occasion a suitable one. We must, however, refer to the extremely interesting article by Mr. JOSEPH CHAMBERLAIN in the current number of the *New Review*. Municipalisation was not so popular among electrical engineers when Mr. CHAMBERLAIN proposed to give power to local authorities to buy up electric supply undertakings at the end of seven years, a term afterwards altered in Committee to fifteen years, and by the House of Lords to twenty-one years; but times have altered, local authorities, once detested, are now courted and flattered, and Mr. CHAMBERLAIN has moderated and matured his views. The ruinous effect of municipal workshops is clearly pointed out in this article, and serious objection made to the action of the London County Council in becoming their own builders and contractors; but what concerns us at present are his observations on municipal technical appointments, and these we quote in full. "A workman with 30s. a week, or a small shopkeeper with £100 or £200 a year, cannot understand the necessity or propriety of paying a town clerk or a chief engineer £2,000 or £3,000 a year. He is very ready to be liberal, and even generous, in dealing with the wages of manual or unskilled labour, but he does not appreciate the exceptional value of special technical gifts and professional experience. In his position as a councillor appointing his subordinates, he finds it difficult to believe that the man can be worth so much more than the master. He is aware that hundreds are ready to take the post for a tenth part of the remuneration, and he forgets that a single mistake or act of carelessness on the part of a high official may cost the community many times as much as the whole of his salary."

The positions of borough surveyors or engineers have long been recognised as honourable distinctions in an important branch of the wide field of engineering, the work necessitating a special training and experience in architecture, building, road making, and occasionally the design, construction, and use of dust destructors; but it seems impossible to believe that a correct appreciation and sound knowledge of high-pressure steam plants and electrical machinery can have been attained, together with the necessary experience in the working, to warrant exclusive authority being held over an electrical engineer able to show proofs of his abilities. Our only object in stating these views is to uphold the dignity of a profession which can no longer be considered as an unimportant or secondary branch of engineering. The training of an electrical engineer is so essentially one long struggle with difficulties, that after emerging from the ordeal the student has a more retentive mind and a greater energy of purpose than the drawing-office pupil who has only developed a pretty skill in colouring tracings. Yet we fear the young electrical engineer will have to continue to fight his way, taking comfort in the thought that municipal works such as tramways, water supplies, &c., may at no distant date become an important part of the utilisation of the energy from the electrical power works which few towns will be so ill-advised as to neglect. The "central station" now so frequently eccentric in position (and occasionally in design) will then bloom into a riper manhood and nobler name of "power house," and we hope by that time the nominal remuneration now offered for services cheerfully undertaken and ably performed will increase to a substantial salary, instead of being a mere honorarium, and thus avert the danger of the "central station" becoming a veritable "work house."

Digitized by Google

The happy combination of the electrician with the mechanical engineer, or *vice versâ*, must result in rapidly developing many improvements in industrial applications of power, and while the field of employment for electrical engineers may, we hope, accommodate a large army of qualified men, work will always be found for those whose tastes or opportunities have led them to seek the calmer life of an electrician. This reminds us that the Commissioners of Sewers of the City of London are now inviting applications for the post of electrical inspector, and as the duties attached to this position are essentially those of a highly qualified electrician—if they are to be properly and perfectly carried out—we have studied with much interest the circular of duties issued to all applicants. These duties are clearly stated, and considerable care has evidently been given to their compilation. The best man will, doubtless, be selected, but we feel some sympathy for the unsuccessful candidates, as it is probable a large number will apply, buoyed up by the easy wording of the list of duties. For example, under the heading of "Machinery," we read, "He must have sufficient knowledge of the practical working of electric plant of all kinds to enable him to understand the uses of the various portions of the generating and distributing apparatus." This condition would, doubtlessly, be easiyl fulfilled in the case of an ordinary continuous-current supply, but no warning is given of the necessity of the candidate having had experience of periodic currents or alternating-current machinery. The testing of meters within this district will also, we fear, require higher qualifications than those enumerated in the list, for no mention is made of the employment of two different types of alternators by the Company supplying the area, and we cannot recommend the task of certifying meters, or of "devising the best means of satisfactorily testing any electrical meter," as an easy matter, except to those who are on speaking terms with phase characteristics, and who have some acquaintance with power factors and other distinguishing features of the harmonic progress of alternate currents. It is, therefore, with some reason that we urge the importance of insisting upon an ascending scale of qualifications for all appointments.

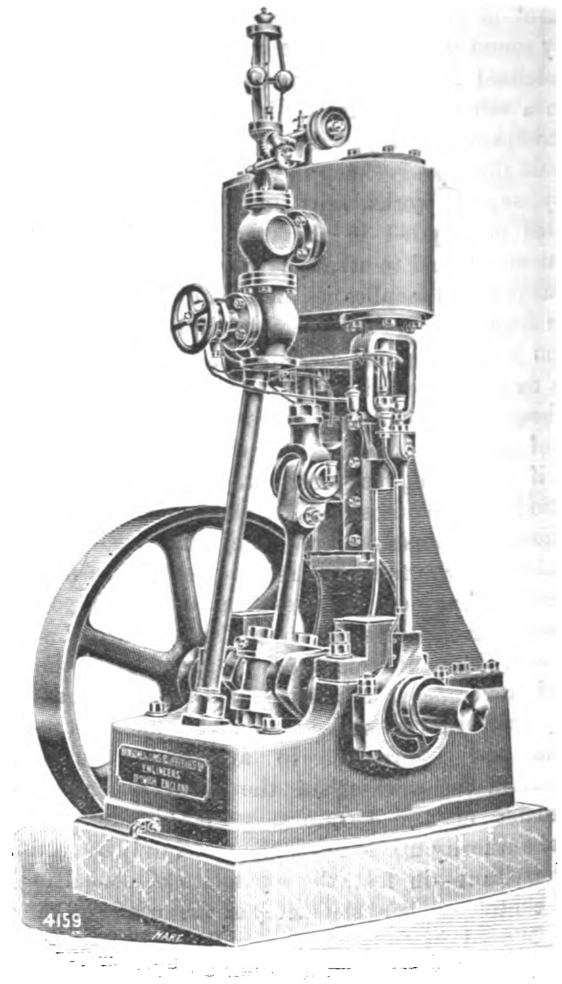
REVIEWS.

Taschenbuch für Monteure elektrischer Beleuchtungsanlagen. By S. Freiherr v. Gaisberg. (R. Oldenbourg, Munich and Leipzig.)

The fact that this "Pocket-book for Wiremen" has reached its eighth edition predisposes the reviewer to a favourable estimate of its contents, and a nearer acquaintance with it has not caused us to form the opposite opinion. It must always be a source of difficulty in the compilation of handbooks of this sort to include only that kind of matter which suits the intelligence of the man who is to use it, but in reading over this work we have several times noticed the inclusion of facts which no ordinary wireman is ever likely to require to know; on the other hand, the total absence of theorising (we have not met a single 4π in the book) is very refreshing. If, however, the wireman requires no figures nor equations, does not want to know the specific resistance of copper, nor the value of π, then a good deal of the rest must also be above his head. The practical hints are valuable, and should be useful to any man of intelligence, though we notice in one place a curious omission. In treating of charging cells, and remarking on the care that must be taken to have the dynamo of the right polarity, the author does not allude to the universal method used for ensuring this, namely, putting the field coils in series with the cells before starting up. On the whole, however, these small defects do not much detract from the value of the book, and we regret that there is little chance of any British workman ever being able to use it.

A HIGH-SPEED VERTICAL STEAM ENGINE.

We give this week an illustration of a high-speed, vertical, inverted, open type of steam engine, specially designed for electric lighting and similar work, by Messrs. Ransomes, Sims, and Jefferies. The illustration shows a pattern constructed for a belt drive, and with throttle valve steam governing; but the engine is also manufactured for direct driving, the engine and dynamo being bolted to the same bed, and may be fitted with a special form of automatic expansion "shaft" governor. This governor acts directly on the piston slide valve. The throttle valve governor is of the well-known Pickering pattern, and is provided with the usual attachment for varying the speed. The engine being of the open type and designed to



Ransomes, Sims and Jefferies High Speed Engine.

run at a high speed, a wrought-iron splash-guard (not shown in our illustration) is provided. Ample bearing surface has been provided for working at high speeds and with considerable steam pressures, the length of each bearing being twice the diameter of the journal. We understand that no tests have yet been made which would show the steam consumption on ordinary loads, and we regret that we are unable to give our readers any information on this point. There is a great field for economical small steam motors of this class, and we hope that the engines of Messrs. Ransomes, Sims and Jefferies will shortly be put under trial with a view to determine their economy.

THE WATERHOUSE ELECTROLYTIC METER.

In view of the comparatively small measure of success which has attended the Edison electrolytic depositing meter, even in the land where it first saw light, and notwithstanding the time and trouble devoted to its perfection, it is a somewhat bold step to seek to introduce into this country such a primitive piece of apparatus as a voltameter-meter, that is to say, one in which the time integral of the current is measured by the

Digitized by Google

volume of the mixed gases given off in a voltameter. We were, however, invited last week to inspect a meter on this principle, and it would certainly seem as if the undoubted advantages of the electrolytic type of meter, namely, cheap first cost, easy calibration, and robust mechanism had been secured at the same time that many of the usually-urged objections to this type had been met. At any rate, English electricity consumers have the satisfaction of knowing that, unless this type of meter survives the stringent examination at the Standardising Laboratory, the Board of Trade will bar its way into general use.

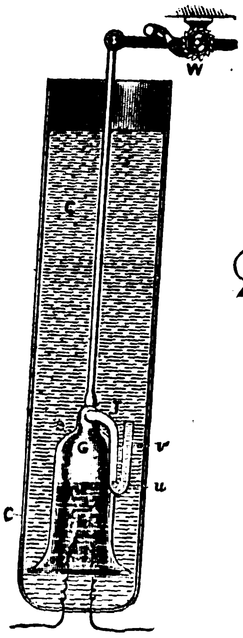


Fig. 1.

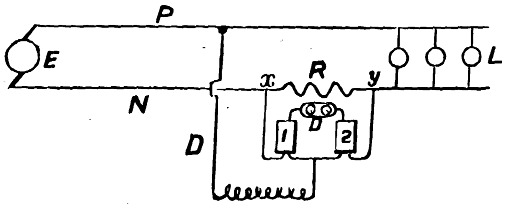

Fig. 2.

The electrolytic cell of the meter, which the Waterhouse Electrometric Syndicate are seeking to put on the market, is shown in Fig. 1. The electrodes are two coils of platinum wire, and the electrolyte is a 12 per cent. solution of sulphuric acid. The mixed gases are collected in the glass bell-jar B, which is fitted with an inverted syphon-tube T. The gases accumulate until they force the fluid down to the bend of the U-tube, when they escape, leaving the collector ready to collect another charge of gas. The rise and fall of the bell-jar in the glass cell actuate a ratchet wheel, and the motion is recorded by a series of dials and pointers in the usual way.

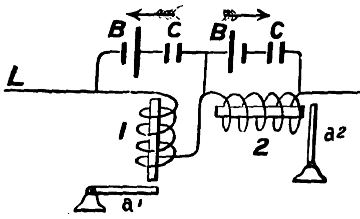

Fig. 3.

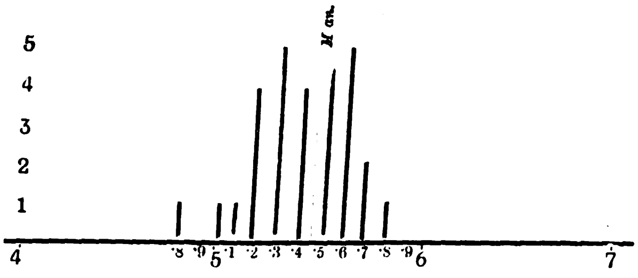
The latest arrangement of the meter circuit is shown diagrammatically in Fig. 2; where E is the source of energy, P and N the positive and negative mains respectively, D a derived circuit of some 1,200 ohms leading to the meter, L the lamps, and R the portion of the main circuit with which the meter-circuit is placed in parallel. When no lamps are alight a special device, not shown, breaks the derived circuit, completing it as soon as one lamp is turned on. If we assume the derived circuit D to be complete but no current to be flowing in the mains, the derived current will divide equally between the two electrolytic cells 1 and 2, the floats of which work the dial *d* in opposite directions, thus nothing is registered. On the other hand, when a current flows in the mains there will be a fall of potential between x and y proportional to the amount of current passing from the lamps. As the fall of pressure over R is limited by the Board of Trade to 0·5 volt, whilst the counter electromotive force offered by the two cells is over 4 volts, it is evident that none of the main current will actually pass through the meter circuit, but, according to the difference of potential between x and y, a greater or less proportion of the total derived circuit current will be diverted through cell 1. The main current is thus measured indirectly by the varying proportions of a practically constant current which is sent through cell 1. In this way the necessity for maintaining by a system of carefully-adjusted resistances the exact proportionality at all temperatures between R and the meter circuit is got over. A meter of this kind, it is obvious, can be made extremely sensitive, since if the derived circuit D is not broken, the minutest fall of pressure over R will have its due changing-over effect. The range also can be made as wide as we please by suitably reducing the value of R. The two branches of the meter circuit being of identical nature, and exposed to identical conditions, temperature effects, so far as resistance is concerned, cancel out, and the errors introduced by volumetric temperature effects are small within the ordinary limits, and easily compensated for. Ordinary changes in the voltage do not materially affect the indications, owing to the fact that, as the meter works differentially, any change in the derived current will balance itself on both sides when no lamps are burning; and when lamps are put on, any increase in the derived current will reduce the changing-over effect, on account of the increased fall of potential over the meter circuit, and *vice versâ*. Curves produced by this meter show it to be capable of considerable accuracy.

Mr. Waterhouse also proposes to apply the voltameter principle, so as to obtain non-wasteful shunts, safety shunts for series motors run on constant current circuits, &c. In Fig. 3 is shown a sort of electrolytically polarised relay arrangement. When the line current is passing from left to right the path through the shunt battery B and electrolytic cell C is taken in preference to that through the high resistance coil 1, and the armature a^1 is left at rest, whilst a^2 is actuated. Just the opposite takes place when the current is sent along the line in the reverse direction.

THE MEAN OF OBSERVATIONS.

One of the diagrams on the walls of the Royal Institution on Friday last, to which Prof. Vernon Boys had no time to allude, was taken from Prof. Poynting's book on "The Mean Density of the Earth." This diagram, which we reproduce, is an interesting mode of exhibiting the distribution of a number of results about the mean. The diagram relates to the 29 results

Mean of Observations.



of Cavendish about the mean value 5·448. The figures 1 to 5 on the left-hand side refer to the number of observations, and the figures on the horizontal scale are the value of the results. The vertical lines in the diagram show that the results, 4·8, 5, 5·1, and 5·8 were obtained on three occasions, 5·7 was obtained twice, 5·2 and 5·4 were each obtained four times, and 5·3, 5·5, and 5·6 appeared five times each. The extremities of these lines would fall very fairly on a symmetrical probability curve, were it not for the single observation 4·8, but consideration of the average deviation shows that such an observation is not highly improbable.

Digitized by Google

The application of the theory of probabilities to the errors of observations, the calculation of the so-called probable error, and the average deviation, involve so much mathematical work that, in many cases, time would much better be spent in making a few more observations, and relying on the arithmetical mean. Some observations, such as transits of Venus, can be made only at rare intervals; others, such as the motions of double stars, consist in the record of slow changes; and others, again, as in the case of Prof. Boys' recent research, consist in weeks or months of preliminary measurements, culminating in a few observations on a single night. In these, examination of the results by the theory of errors is of great importance. One of the important lessons taught by the theory of errors is the distinction between an error and a mistake. Cavendish, with all his experimental care, and painstaking calculations, made a mistake in adding up the results of these observations, to get the mean. The plotting of results on squared paper, even when no graphical record is wanted, is a valuable safeguard against mistakes, and this simple method of showing the distribution of results about the mean, deserves to be better known, and to be frequently used. The theory of probability and a large number of its applications has been recently treated by Prof. Karl Pearson from a geometrical point of view, and when his Gresham College lectures on this extremely interesting topic are published, they will no doubt do much to popularise a subject which is generally presented in a most unattractive form.

A METHOD FOR THE TREATMENT OF ROTATING OR ALTERNATING VECTORS, WITH AN APPLICATION TO ALTERNATE CURRENT MOTORS.

BY PROF. GALILEO FERRARIS.

(*Concluded from page 153.*)

17. In that which precedes, we have considered the relation between the couple of rotation and the frequency u of the *relative motion* of the rotating field with respect to the armature. To find now the relation between the couple and the velocity of the rotation of the armature, it is enough to observe that if we represent, as usual, by n the frequency of the rotating magnetic field, and represent by m the frequency of the rotation of the armature, or the number of turns which the armature makes in 1″, we have

$$u = n - m.$$

Inserting this value into (1) we have

$$K = \pi N B^2 S^2 \frac{r(n-m)}{r^2 + 4\pi^2 L^2 (n-m)^2}, \quad . \quad . \quad . \quad . \quad . \quad (2)$$

which gives the required relation. The curve into which this formula is converted when we take as ordinate the couple K, and as abscissa the frequency m of the rotation of the armature, can be deduced at once from the curve $C_1 O C_2$ of Fig. 14; but this is the same curve only referred to other axes of co-ordinates. In fact, let there be set out on $O X'$ a length $O O_1 = n$, and let p be the foot of the ordinate of any point P of the curve $C_1 C_2$, then we have $O_1 p = O O_1 - O p = n - u = m$. Then take the point O_1 as the origin of the co-ordinates, the straight line $O_1 Y_1$ parallel to $O Y$ as axis of the ordinates, and take $O_1 O X$, directed from right to left, as positive part of the axis of the abscissæ; the line $C_1 M' O P M Q C_2$ is then without doubt such that its points which have for co-ordinates the values of m and of K.

The curve exhibits the properties appertaining to the motor. Two cases must be distinguished; the case of $n \leqq \frac{1}{2\pi} \frac{r}{L}$, and that of $n > \frac{1}{2\pi} \frac{r}{L}$.

In the first case, when $n \leqq \frac{1}{2\pi} \frac{r}{L}$; when, therefore, $2\pi n L \leqq r$, we have $O O_1 \leqq O q$. The origin O_1 falls to the left of q or at q. Then K has the maximum value for $m=0$. The motor couple is at a maximum when the armature no longer turns, and is at its maximum at the moment of starting. If when starting from rest, or from $m=0$, m is made to increase, K diminishes down to nothing for $m=n$ and to become negative for $m > n$. The running of the motor is steady. In fact, the resisting couple increases, and if meanwhile m diminishes, pP increases; moreover, the motor couple K increases also, until it becomes equal to the new value of the resisting couple. If *vice versâ* the resisting couple diminishes, and if meanwhile the velocity augments, p P diminishes, or also diminishes the motor couple K until it re-establishes the equilibrium.

In the second case, when $n > \frac{1}{2\pi} \frac{r}{L}$, or when $2 \pi n L > r$, we have $O O_1, > O q$. The origin O_1 falls to the right of q. Then for $m = 0$ the motor couple K has a value $O_1 Q$ less than the maximum q M. If m is made to increase, starting from the value zero, K commences to increase, and attains the maximum value q M when $m = O_1 q = O_1 O - O q = n - \frac{r}{2 L \pi}$. After that, if m again increases K diminishes down to nothing for $m=n$, and becomes negative for $m > n$. The working of the motor is steady, for $m > O_1 q$, or for $m > n - \frac{r}{2\pi L}$, because then, as in the preceding case, an augmentation of the resisting couple, provoking a diminution of m, gives place to a diminution of K, by which the equilibrium is re-established. But for $m \leqq n - \frac{r}{2\pi L}$ the working of the motor is unsteady. If, in fact, by an augmentation of the resisting couple a diminution of m is proved, this diminution gives place to a diminution of the motor couple K, and therefore to a further diminution of m; and this effect is reproduced and multiplied until the motor is brought to rest.

In all the cases K is reduced to zero by $m = n$, and becomes negative for $m > n$. That is to say, that in no case can an armature turn itself with a frequency greater than that of the current, unless by means of a motor couple applied from without to the shaft, or without an expenditure of work. The couple necessary for that has the maximum moment q' M′ when

$$m = O_1 O + O q' = O_1 O + O q = n + \frac{r}{2\pi L}.$$

In the second case before considered, when $2\pi n L > r$, it may happen (and it happens commonly when n is great) that the value O_1 Q of K corresponding to $m=0$ is insufficient for the starting of the motor. Then the starting may be aided by inserting a non-inductive resistance into the circuit of the armature, thus making r increase without augmenting L. In fact the value K_0 of K which formula (2) gives for $m=0$, a value which can be written

$$K_0 = \pi N B^2 S^2 \frac{n}{r + \frac{4\pi^2 n^2 L^2}{r}},$$

is greatest for $r = 2\pi n L$. And moreover, since r is less than $2\pi n L$, it increases with the increase of r. The efficacy of this artifice for increasing K_0 at the moment of starting is so much the greater, the greater the frequency n of the current used, and it is precisely in the case of great frequencies that it may be necessary. The motor may be able to start itself without special provision, and has a more steady working when the frequency n is small.

18. *Closed Armature placed in an Alternating Magnetic Field. Monophase Asynchronous Motors.*—Let us imagine, now, that the same armature already considered in Article 15 is situated no longer in a rotating magnetic field, but in an alternating magnetic field of fixed direction, that which now occurs may be easily deduced from what has been already said. The alternating magnetic field is equal to two fields rotating in opposite directions; similarly, the currents induced in the armature are equivalent to two magnets rotating in opposite directions. There acts, therefore, upon the armature a couple equal to the resultant of those exercised by the two fields upon the two rotating magnets. But by what was said in Article 12, case 3rd, the mean values of the couples produced by any of the fields on the magnet rotating in the opposite sense are equal to zero; hence the mean value of the moment of the resultant couple acting in total on the armature is simply equal to the difference between that of the couple which the field rotating to the right exercises on the magnet rotating to the right, and that of the couple which the field rotating to the left produces on the magnet rotating to the left. Given K_1 and K_2, the moment of these two couples, and given K, the moment of the resulting couple acting on the armature (taken as positive when the couple is directed towards the right), we have

$$K = K_1 - K_2. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

The couples K_1 and K_2 can be calculated by the formula (1) of Art. 16. We should remember at this point that B represents the value of the magnetic induction in each of the two rotating fields into which the given alternating field is resolved. It may also be noted that the maximum value of the magnetic induction in this last may be represented by 2 B. We should then substitute successively in the formula for the frequency u of the relative motion, the values u_1 and u_2 corresponding to the movements which the two rotating fields have *relatively to the armature*. Now if it is supposed that the armature turns *towards the right* with a frequency m, and we represent by n the frequency of the alternating magnetic field, we have

$$u_1 = n - m, \quad u_2 = n + m;$$

Digitized by Google

thence,
$$K_1 = \pi N B^2 S^2 \frac{r(n-m)}{r^2+4\pi^2 L^2(n-m)^2}, \quad . \quad . \quad . \quad . \quad (4)$$
$$K_2 = \pi N B^2 S^2 \frac{r(n+m)}{r^2+4\pi^2 L^2(n+m)^2}, \quad . \quad . \quad . \quad . \quad (5)$$
and, finally,
$$K = \pi N B^2 S^2 r \left[\frac{n-m}{r^2+4\pi^2 L^2(n-m)^2} - \frac{n+m}{r^2+4\pi^2 L^2(n+m)^2} \right]. \quad . \quad (6)$$

The curves which represent the relations between K_1, K_2, K, and the frequency m of the rotation of the armature, can be copied at once from $C_1 O C_2$, which in Fig. 14 represents the equation (1): The $C_1 O C_2$ is reproduced and marked with the same letters as in Fig. 15, where, as in 14, the point O is the origin of u; and the point O_1, at the distance $O O_1$, which is at a distance n from O, is the origin of m.

If we take (Fig. 15) $O_1 p_1 = O_1 p_2 = m$, and draw the corresponding ordinates $p_1 P_1$ and $p_2 P_2$; we have at once: $O p_1 = O O_1 - p_1 O_1 = n - m$ and $O p_2 = O O_1 + O_1 p_2 = n + m$. Thence the ordinates $p_1 P_1$ and $p_2 P_2$ represent respectively K_1 and K_2. In order to have K alone it is enough to subtract $p_2 P_2$ from $p_1 P_1$. If we cut off from $p_1 P_1$ the segment $P_1 P = p_2 P_2$, the remaining segment $p_1 P$ represents K, and the point P is a point of the curve which gives K as a function of m, referred to the axes of co-ordinates $O_1 X$ and $O_1 Y_1$.

What the form of the curve K should be we see also more clearly if we draw the line $Q P_0 C_0$ symmetric, with respect to the axis $O_1 Y_1$, to the portion $Q P_2 C_2$ of $C_1 O C_2$. Then there results the value of K corresponding to the value $O_1 p_1$ of m, represented by the segment $P_0 P_1$, comprised between the two lines $Q P_1 C_1$ and $Q P_0 C_0$. This segment is equal to the ordinate $p_1 P$ of the curve K, corresponding to the abscissa $m = O_1 p_1$. The examination of the curve K shows clearly the principal property of the motor. The moment K of the couple acting on the armature is zero when $m=0$, or when the armature is at rest; but if this turns suddenly K assumes a value different from zero, and if the frequency m of the rotation does not exceed the value represented in the figure by $O_1 A$, it is positive, or the couple has the same direction of rotation, it is a motor couple. If, starting from rest, the armature takes an increasing velocity, the couple, zero at the beginning, goes on increasing finally to a maximum, reaching which, if m also increases, it thence diminishes rapidly and is reduced again to zero when m reaches a determinate value $O_1 A$ somewhat lower than n. For the values of m greater than $O_1 A$, the couple K becomes and remains always negative, or is opposed to the rotation, it being a resisting couple.

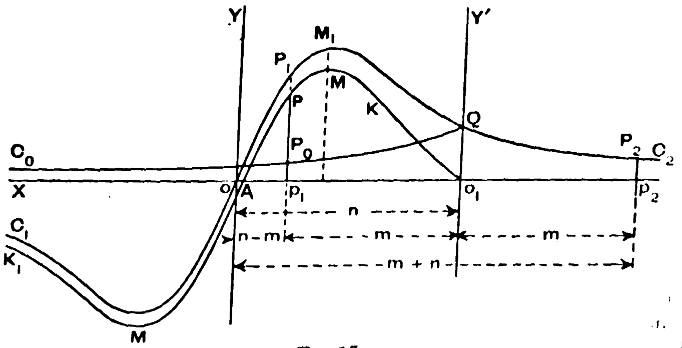


Fig. 15.

The descending portion of the curve M M′ corresponds to a steady running of the motor. In fact, if, whilst the armature turns with the frequency $m = O_1 p_1$, and with the motor couple $p_1 P$, the resisting couple begins to increase somewhat, and becomes greater than $p_1 P$, the velocity of the armature diminishes, $O_1 p_1$ diminishes, and the motor couple $p_1 P$ increases up to the re-establishment of equilibrium. If similarly the resisting couple begins to diminish, the armature is accelerated p_1, is projected towards the left, and the motor couple $p_1 P$ diminishes also.

On the other hand, the working is not steady for the ascending portion $O_1 M$ of the line, or for values of m less than that to which the maximum of the motor couple corresponds. Then, in fact, a diminution of velocity due to an excess of the resisting couple over the motor couple, provokes a diminution of this last, and, therefore, produces a further diminution of velocity, which is multiplied and continues until the armature stops completely. The descending portion of the curve K, for which the working is stable, has an inclination slightly less than that of the neighbouring curve $C_1 O C_2$, and the inclination of this at point O (Art. 16) is equal to $\frac{\pi N B^2 S^2}{r}$. Similarly, the maximum point of the curve K is but little distant from that of the curve $C_1 O C_2$, the abscissa of which is $n - \frac{1}{2\pi} \frac{r}{L}$ (Art. 16). Hence, if the resistance r is small, the useful portion of the curve K has a large slope; and, if the self-induction L is not very small, the values of m corresponding to it are comprised within limits very close to one another. This happens pretty often in practice; the motor is truly asynchronous, but the limits between which the velocity can vary compatibly with steadiness of working are frequently much restricted. The line $Q P_1 O C_1$ (Fig. 15) is that which would represent the relation between the motor couple and the velocity when the armature, instead of being situated in an alternating field where the magnetic induction has the maximum value 2 B, might be situated in a simple rotating magnetic field, where the induction would have the constant value B. Meanwhile Fig. 15 shows clearly the analogy and the difference which exist between the properties of an asynchronous motor with alternating field and those of a motor with rotating field.

If n is not very small, and if the resistance r of the armature is as is usual somewhat small, the two curves $Q P_1 O C_1$ and $O_1 K P A K_1$ run very close to one another for all the values of m superior to those for which the motors commenced to have a steady working. Thence for all the velocities compatible with a steady working the monophase motor behaves, approximately, like the motor with rotating field; only the motor couple is in it somewhat smaller, and is reduced to zero for a value of m somewhat less than n. The two curves diverge most from one another in the parts corresponding to the lesser velocity. The charcteristic difference which follows therefrom is that for $m=0$, the moment of the motor couple, which in the motor with rotating field may have a value $O_1 Q$, which is fairly high, is zero in the monophase motor. The motor with rotating field may start of itself, the monophase motor cannot do so.

The expression (6) for the motor couple of a monophase motor can also easily be found, without going back to our method of treatment of alternating vectors; it was, in fact, demonstrated by

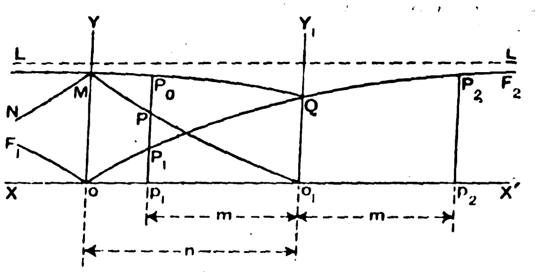

Fig. 16.

Dr. J. Sahulka directly by a purely algebraic method (1), and is noteworthy. But the essential advantage of our method is, that it appeals to a physical reasoning of facts, and shows clearly the relations which exist between a motor with alternating field and one with rotating field. A motor with alternating field presents itself as a motor with differential rotating field; its properties are derived directly from those of the motors with rotating field.

19. Various additional considerations present themselves which would be hardly obvious by the ordinary analytical treatment. One of these refers to the nature of the currents in the armature, and to the reaction of these on the inductor. The currents in the armature are equivalent, as we have shown, to two magnets rotating in opposite directions. The vectors which represent these magnets turn in space with equal angular velocity and precisely with the frequency n of the alternating magnetic field; they are, therefore (Art. 4, b), equivalent to the system of a rotating vector and of an alternating vector. That is to say, that the currents induced in the armature produce in space a flux of magnetic induction, which may be considered as resulting from the superposition of two fluxes, one of constant value and rotating in direction, the other of alternating value and in a fixed direction. Let us consider these two fluxes successively.

Rotating Flux.—The rotating flux is proportional to the difference between the *absolute values* of the vectors which represent the two rotating magnets equivalent to the currents of the armature (Art. 4, b). Therefore it is proportional to
$$y_1 - y_2,$$
where y_1 and y_2 represent the *absolute* values, coresponding to
$$u = n - m \text{ and to } u = n + m,$$
of the quantity y, which is the function of u given by the formula
$$y = \frac{u}{\sqrt{r^2 + 4\pi^2 u^2 L^2}}.$$

In order to give an idea of the mode of variation of it as a function of m, it is enough to consider the curve of y. Now y has

Digitized by Google

absolute values for u and for $-u$, which are equal. It is equal to zero, for $u=0$, increases with the increase of u, and for $u=\pm\infty$ tends asymptotically towards the value $\frac{1}{2\pi L}$ as its limit. If, then (Fig. 16), we take as abscissæ the values of u, and as ordinates the absolute values of y, and if we take as origin the point O, and as the positive direction of the axis of u the line O X′, we find the line $F_1 O F_2$, which has for asymptote the straight line, L L, parallel to the axis of the abscissæ. In order to find $y_1 - y_2$ we take $O O_1 = n$ and $O_1 p_1 = O_1 p_2 = m$; there results $O p_1 = n - m$, $O p_2 = n + m$, whence the ordinates $p_1 P_1$ and $p_2 P_2$ represent y_1 and y_2, and we have at once $y_1 - y_2 = p_1 P_1 - p_2 P_2 = -(p_2 P_2 - p_1 P_1)$.

The mode of variation of this difference appears clear if we draw in $Q P_0 M$ the line symmetric with respect to $O_1 Y_1$ to $Q P_2 F_2$. Now we have $y_1 - y_2 = - P_1 P_0$. We can, if we wish, take this length as ordinate, and thus find, that taking as origin the point O_1, as axis of the ordinates the line $O_1 Y_1$ and as the positive direction of the axis of abscissæ $O_1 X$, $y_1 - y_2$ is represented as a function of m by the curve $O_1 P M N$.

The sign ($-$) of the value derived from the condition $p_2 P_2 > p_1 P_1$ tells that the flux under consideration rotates towards the left, or in the direction opposed to the movement of the armature. Now this flux, which turns towards the left, produces in the metal of the fixed part of the machine, induced currents on which it then exercises forces tending to draw it from its proper rotation, towards the left. Thence, *vice versâ*, the induced currents in the fixed part of the machine solicit the armature to turn towards the right, in the direction in which it already moves. Whence results that the rotating flux due to the currents in the armature provokes induced currents, which help the rotation, and give place to a couple, which joins to the principal couple of which we spoke in the preceding article. The value of the couple due to the induced currents varies with the variation of m, and increases with the increase of the ordinate $p_1 P$ of the line $O_1 M N$. It is zero for $m=0$ and greatest for $m=n$. Owing to it, the total couple acting on the armature instead of being reduced to zero for $m = O_1 A$ (Fig. 15), is not reduced to zero for any value a little larger, a little nearer to n.

Alternating Flux.—The alternating vector resulting from the composition of two vectors rotating in opposite senses, has an amplitude equal to double the smallest of the two component vectors (Art. 4). However, the alternating flux is proportional to

$$\frac{n-m}{\sqrt{r^2 + 4\pi^2 L^2 (n-m)^2}}.$$

It can be zero only for $m=n$.

THE WORK OF HERTZ.*

(Continued from page 155.)

Zinc Discharging Negative — Electricity in Light; Gold Leaf Electroscope; Glass and Quartz Panes; Quartz Prism.

Take a piece of zinc, clean it with emery paper, connect it to a gold leaf electroscope, and expose it to an arc lamp. If charged positively nothing appears to happen, the action is very slow; but a negative charge leaks away in a few seconds if the light is bright. Any source of light rich in ultra-violet rays will do; the light from a spark is perhaps most powerful of all. A pane of glass cuts off all the action; so does atmospheric air in sufficient thickness (at any rate, town air), hence sunlight is not powerful. A pane of quartz transmits the action almost undiminished, but fluor-spar may be more transparent still. Condensing the arc rays with a quartz lens and analysing them with a quartz prism or reflection grating, we find that the most effective part of the light is high up in the ultra-violet, surprisingly far beyond the limits of the visible spectrum† (Figs. 7 and 8).

This is rather a digression, but I have taken some pains to show it properly because of the interest betrayed by Lord Kelvin on this matter, and the caution which he felt about accepting the results of the Continental experimenters too hastily.

It is probably a chemical phenomenon, and I am disposed to express it as a modification of the volta contact effect* with illumination.

Return now to the Hertz vibrator, or Leyden jar with its coatings well separated, so that we can get into its electric as well as its

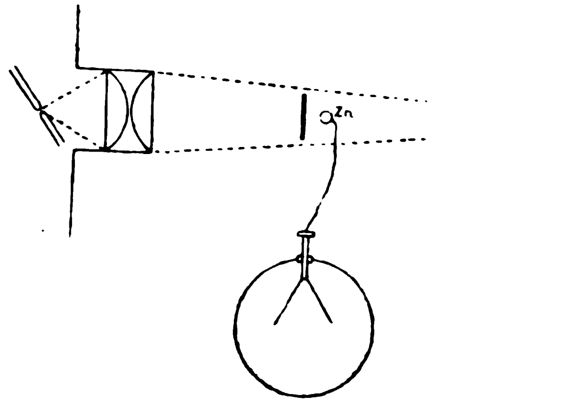

Fig. 7.—Zinc Rod with Glass Screen.

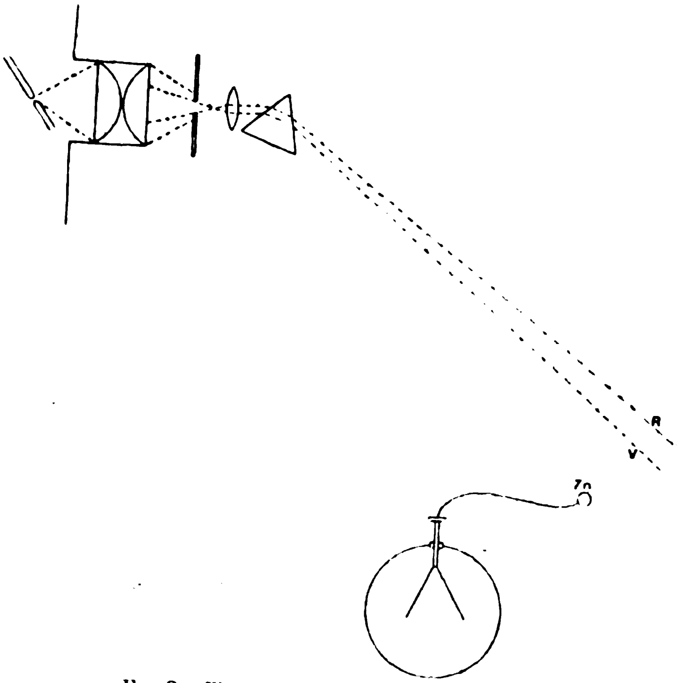

Fig. 8.—Zinc Rod with Ultra-violet Light.

magnetic field. Here is a great one giving waves 30 metres long, radiating while it lasts with an activity of 100 H.P., and making ten million complete electric vibrations per second.

Large Hertz Vibrator in action; Abel's Fuse; Vacuum Tube; Strike an Arc.

Its great radiating power damps it down very rapidly, so that it does not make above two or three swings; but nevertheless, each time it is excited, sparks can be drawn from most of the reasonably elongated conductors in this theatre.

A suitably situated gas-leak can be ignited by these induced sparks. An Abel's fuse connecting the water pipes with the gas pipes will blow off; vacuum tubes connected to nothing will glow (this fact has

* A lecture delivered at the Royal Institution on Friday, June 1st, by Prof. Oliver Lodge, F.R.S., ably assisted during both preparation and performance by Mr. Edward E. Robinson.

† While preparing for the lecture it occurred to me to try, if possible, during the lecture itself, some new experiments on the effect of light on negatively charged bits of rock and ice, because if the effect is not limited to metals it must be important in connection with atmospheric electricity. When Mr. Branly coated an aluminium plate with an insulating varnish, he found that its charge was able to soak in and out of the varnish during illumination (*Comptes Rendus*, Vol. CX., p. 898, 1890). Now, the mountain tops of a negatively charged earth are exposed to very ultra-violet rays, and the air is a dielectric in which quiet up-carrying and sudden downpour of electricity could go on in a manner not very unlike the well-known behaviour of water vapour; and this perhaps may be the reason, or one of the reasons, why it is not unusual to experience a thunderstorm after a few fine days. I have now tried these experiments on such geological fragments as were handy, and find that many of them discharge negative electricity under the action of a naked arc, especially from the side of the specimens which was somewhat dusty, but that when wet they discharge much less rapidly, and when positively charged hardly at all. Ice and garden soil discharge negative electrification, too, under ultra-violet illumination, but not so quickly as limestone, mica schist, ferruginous quartz, clay, and some other specimens. Granite barely acts; it seems to insulate too well. The ice and soil were tried in their usual moist condition, but, when thoroughly dry, soil discharges quite rapidly. No rock tested was found to discharge as quickly as does a surface of perfectly bright metal, such as iron, but many discharged much more quickly than ordinary dull iron, and rather more quickly than when the bright iron surface was thinly oiled or wetted with water. To-day (June 5) I find that the leaves of the geranium discharge positive electrification five times as quickly as negative, under the action of an arc-light, and that glass cuts the effect off while quartz transmits it.

Digitized by Google

been familiar to all who have worked with Hertz waves since 1889); electric leads, if anywhere near each other, as they are in some incandescent lamp-holders, may spark across to each other, thus striking an arc and blowing their fuses.

This blowing of fuses by electric radiation frequently happened at Liverpool till the suspensions of the theatre lamps were altered.

The striking of an arc by the little reverberating sparks between two carbon points connected with the 100 volt mains I incidentally now demonstrate.

sensitive galvanometer could indicate that a feeble spark had passed, by reason of the consequent disturbance of electrical equilibrium which settled down again through the galvanometer. This was the method he used in this theatre four years ago. Blyth used a one-sided electrometer, and young Bjerkness has greatly developed this method (Fig. 14), abolishing the need for a spark, and making the electrometer metrical, integrating, and satisfactory.† With this detector many measurements have been made at Bonn

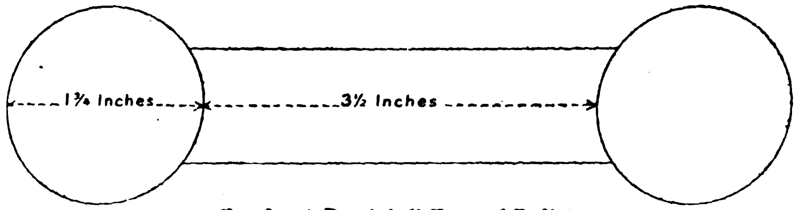

FIG. 9.—A Dumb-bell Form of Radiator.

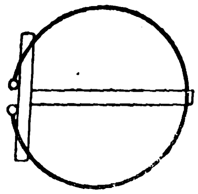

FIG. 11.—Circular Resonator.

There are some who think that lightning flashes can do none of these secondary things. They are mistaken.

On the table are specimens of various emitters and receivers such as have been used by different people (*see* Table). The orthodox Hertz radiator of dumb-bell type (Fig. 9), the orthodox Hertz receivers (Fig. 10); a circular ring (Fig. 11) for interference experiments, because it is but little damped, and a straight wire for receiving at a distance, because it is a much better absorber.

by Bjerkness, Yule, Barton, and others on waves concentrated and kept from space dissipation by guiding wires.

Mr. Boys has experimented on the mechanical force exerted by electrical surgings, and Hertz also made observations of the same kind.

Going back to older methods of detecting electrical radiation, we have, most important of all, a discovery made long before man existed, by a creature that developed a sensitive cavity on its skin ;

Detectors of Radiation.

× The cross against the frog's leg indicates that it does not appear really to respond to radiation, unless stimulated in some secondary manner. The names against the other things are unimportant, but suggest the persons who applied the detector to electric radiation. The interrogation mark against Selenium indicates that its position in the microphonic column may be doubtful.

Beside these are the spheres and ellipsoids (or elliptical plates), which I have mainly used, because they are powerful radiators and absorbers, and because their theory has been worked out by Horace Lamb and J. J. Thomson. Also dumb-bells without air-gap, and many other shapes, the most recent of mine being the inside of a hollow cylinder with sparks at ends of a diameter ; this (Fig. 12) being a feeble radiator, but a very persistent vibrator,* and, therefore, well adapted for interference and diffraction experiments. But, indeed, spheres can be made to vibrate longer than usual by putting them into copper hats or enclosures, in which an aperture of varying size can be made to let the waves out.

Many of these senders will do for receivers too, giving off sparks to other insulated bodies or to earth ; but, besides the Hertz type

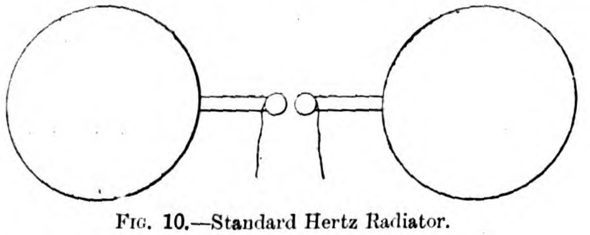

FIG. 10.—Standard Hertz Radiator.

of receiver, many other detectors of radiation have been employed. Vacuum tubes can be used, either directly or on the trigger principle, as by Zehnder (Fig. 13),† the resonator spark precipitating a discharge from some auxiliary battery or source of energy, and so making a feeble disturbance very visible. Explosives may be used for the same purpose, either in the form of mixed water-gases or in the form of an Abel's fuse. Fitzgerald found that a tremendously

caused in a platinum wire, a kind of early and sensitive form of Cardew voltmeter.

Going back to the physiological method of detecting surgings, Hertz tried the frog's-leg nerve and muscle preparation, which to the steadier types of electrical stimulus is so surpassingly sensitive, and to which we owe the discovery of current electricity. But he failed to get any result. Ritter has succeeded; but, in my experience, failing in the normal and proper result. Working with my colleague Prof. Gotch, at Liverpool, I too have tried the nerve and muscle preparation of the frog (Fig. 15), and we find that an excessively violent stimulus of a rapidly alternating character, if pure and unaccompanied by secondary actions, produces no effect—no stimulating effect, that is, even though the voltage is so high that sparks are ready to jump between the needles in direct contact with the nerve.

All that such oscillations do, if continued, is to produce a temporary paralysis or fatigue of the nerve, so that it is unable to transmit the nerve impulses evoked by other stimuli, from which paralysis it recovers readily enough in course of time.

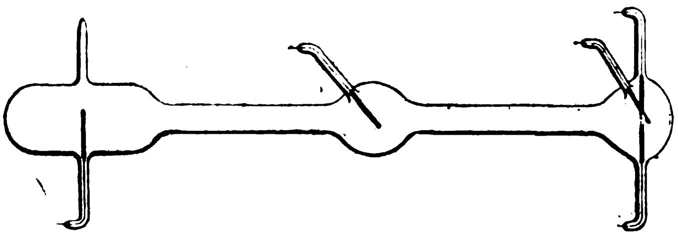

FIG. 13.—Zehnder's Trigger Tube. Half Natural Size.

This has been expected from experiments on human beings, such experiments as Tesla's and those of d'Arsonval. But an entire animal is not at all a satisfactory instrument wherewith to attack the question; its nerves are so embedded in conducting tissues that it may easily be doubted whether the alternating type of stimulus ever reaches them at all. By dissecting out a nerve and muscle from a deceased frog after the historic manner of physiologists, and applying the stimulus direct to the nerve, at the same time as some other well known $\frac{1}{100}$th of a volt stimulus is applied to another part of the same nerve further from the muscle, it can be shown that rapid electric alternations, if entirely unaccompanied by static charge or by resultant algebraic electric transmission, evoke no excitatory response until they are so violent as to give rise to secondary effects such as heat or mechanical shock. Yet, notwithstanding this inaction, they gradually and slowly exert a paralysing or obstructive action on the portion of the nerve to which they are applied, so that the nerve impulse excited by the feeble just perceptible $\frac{1}{100}$th-volt stimulus above is gradually throttled on its way down to the muscle, and remains so throttled for a time varying from a few minutes to an hour after the cessation of the violence.

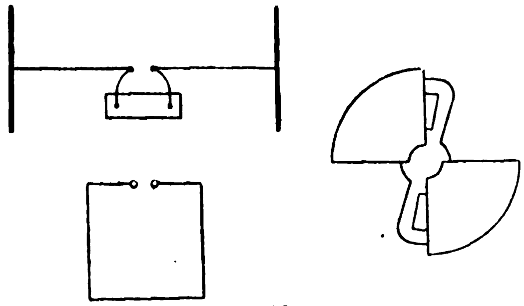

FIG. 14.

I had intended to exhibit this effect, which is very marked and definite, but it is impossible to show everything in the time at my disposal.

Air Gap and Electroscope charged by Glass Rod and discharged by moderately distant Sphere excited by Coil.

Among trigger methods of detecting electric radiation, I have spoken of the Zehnder vacuum tubes; another method is one used by Boltzmann.* A pile of several hundred volts is on the verge of charging an electroscope through an air gap just too wide to break down. Very slight electric surgings precipitate the discharge across the gap, and the leaves diverge. I show this in a modified and simple form. On the cap of an electroscope is placed a highly-polished knob or rounded end connected to the sole, and just not touching the cap (Fig. 16). Such an electroscope overflows suddenly and completely with any gentle rise of potential. Bring excited glass near it, the leaves diverge gradually and then suddenly collapse, because the air space snaps; remove the glass, and they rediverge with negative electricity; the knob above the cap being then charged positively, and to the verge of sparking. In this condition any electrical waves, collected if weak by a foot or so of wire projecting from the cap, will discharge the electroscope by exciting surgings in the wire, and so breaking down the air-gap. The chief interest about this experiment seems to me the extremely definite dielectric strength of so infinitesimal an air space. Moreover, it is a detector for Hertz waves that might have been used last century; it might have been used by Benjamin Franklin.

For to excite them no coil or anything complicated is necessary; it is sufficient to flick a metal sphere or cylinder with a silk handkerchief and then discharge it with a well-polished knob. If it is not well polished the discharge is comparatively gradual, and the vibrations are weak; the more polished are the sides of an air-gap, the more sudden is the collapse and the more vigorous the consequent radiation, especially the radiation of high frequency, the higher harmonics of the disturbance.

For delicate experiments it is sometimes well to repolish the knobs every hour or so. For metrical experiments it is often

FIG. 15.—Experiment of Gotch and Lodge on the physiological effect of rapid pure electric alternations. Nerve and muscle preparation, with four needles or else non-polarisable electrodes applied to the nerve. C and D are the terminals of a rapidly alternating electric current from a conductor at zero potential, while A and B are the terminals of an ordinary very weak galvanic or induction coil stimulus only just sufficient to make the muscle twitch.

better to let the knobs get into a less efficient but more permanent state. This is true of all senders or radiators. For the generation of the, so to speak, "infra-red" Hertz waves any knobs will do, but to generate the "ultra-violet" high polish is essential.

Microphonic Detectors.

Receivers or detectors, which for the present I temporarily call microphonic, are liable to respond best to the more rapid vibrations. Their sensitiveness is to me surprising, though of course it does not approach the sensitiveness of the eye; at the same time, I am by no means sure that the eye differs from them in kind. It is these detectors that I wish specially to bring to your notice.

Prof. Minchin, whose long and patient work in connection with photo-electricity is now becoming known, and who has devised an instrument more sensitive to radiation than even Boys' radiomicrometer, in that it responds to the radiation of a star while the radiomicrometer does not, found some years ago that some of his slight excitable cells lost their sensitiveness capriciously on tapping, and later he found that they frequently regained it again while Mr. Gregory's Hertz-wave experiments were going on in the same room.

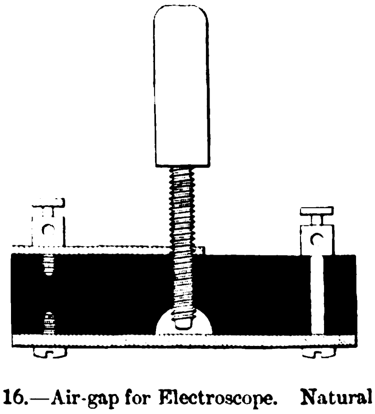

FIG. 16.—Air-gap for Electroscope. Natural Size.

These "impulsion-cells," as he terms them, are troublesome things for ordinary persons to make and work with—at least I have never presumed to try—but in Mr. Minchin's hands they are surprisingly sensitive to electric waves.*

The sensitiveness of selenium to light is known to everyone, and Mr. Shelford Bidwell has made experiments on the variations of conductivity exhibited by a mixture of sulphur and carbon.

Nearly four years ago M. Edouard Branly found that a burnished coat of porphyrised copper spread on glass diminished its resistance enormously, from some millions to some hundreds of ohms when it was exposed to the neigbourhood, even the distant neighbourhood, of Leyden jars or coil sparks. He likewise found that a tube of metallic filings behaved similarly, but that this recovered its original resistance on shaking. Mr. Croft exhibited this fact

* *Wied. Ann.*, XL., p. 399.

* *Phil. Mag.*, Vol. XXXI., p. 223.

Digitized by Google

recently at the Physical Society. Branly also mades pastes and solid rods of filings in Canada balsam and in sulphur and found them likewise sensitive.*

With me the matter arose somewhat differently, as an outcome of the air-gap detector employed with an electroscope by Boltzmann. For I had observed in 1889 that two knobs sufficiently close together, far too close to stand any voltage such as an electroscope can show, could, when a spark passed between them, actually cohere; conducting an ordinary bell-ringing current if a single voltaic cell was in circuit; and, if there were no such cell, exhibiting an electromotive force of their own sufficient to disturb a low resistance galvanometer vigorously, and sometimes requiring a faintly perceptible amount of force to detach them. The experiment was described to the Institution of Electrical Engineers,† and Prof. Hughes said he had observed the same thing.

Coherer in open, responding to Feeble Stimuli; Small Sphere Gas-lighter; Distant Sphere Electrophorus.

Well, this arrangement, which I call a coherer, is the most astonishingly sensitive detector of Hertz waves. It differs from the actual air-gap in that the insulating film is not really insulating; the

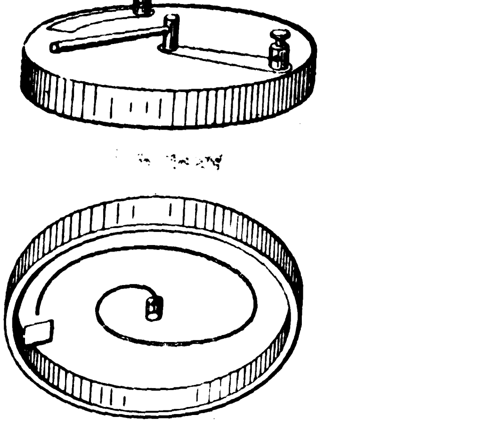

FIG. 17.—Wire Coherer, consisting of a spiral of thin iron wire mounted on an adjustable spindle and an aluminium plate. When the lever is moved clockwise, against a stop not shown in the illustration, the tip of the iron wire presses very gently against the aluminium plate.

film breaks down not only much more easily, but also in a less discontinuous and more permanent manner than an air-gap. A tube of filings, being a series of bad contacts, clearly works on the same plan; and though a tube of filings is by no means so sensitive, yet it is in many respects easier to work with, and, except for very feeble stimuli, is more metrical. If the filings used are coarse, say turnings or borings, the tube approximates to a single coherer; if they are fine, it has a larger range of sensibility. In every case what these receivers feel are sudden jerks of current; smooth

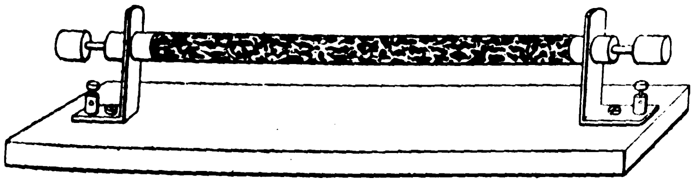

FIG. 18.—Iron Borings Coherer, one-third natural size.

sinuous vibrations are ineffective. They seem to me to respond best to waves a few inches long, but doubtless that is determined chiefly by the dimensions of some conductor with which they happen to be associated. (Figs. 17 and 18.)

Filings in open, responding to Sphere, to Electrophorus, to Spark from Gold-leaf Electroscope.

I picture to myself the action as follows: Suppose two fairly clean pieces of metal in light contact—say two pieces of iron—connected to a single voltaic cell; a film of what may be called oxide intervenes between the surfaces, so that only an insignificant current is allowed to pass, because a volt or two is insufficient to break down the insulating film except perhaps at one or two atoms. If the film is not permitted to conduct at all, it is not very sensitive; the most sensitive condition is attained when an infinitesimal current passes, strong enough just to show on a moderate galvanometer.

Now let the slightest surging occur, say by reason of a sphere being charged and discharged at a distance of forty yards, the film at once breaks down--perhaps not completely, that is a question of intensity—but permanently. As I imagine, more molecules get within each other's range, incipient cohesion sets in, and the momentary electric quiver acts as it were as a flux. It is a singular variety of electric welding. A stronger stimulus enables more molecules to hold on, the process is surprisingly metrical, and as far as I roughly know at present, the change of resistance is proportional to the energy of the electric radiation from a source of given frequency.

It is to be specially noted that the battery current is not needed to effect the cohesion, only to demonstrate it. The battery can be applied after the spark has occurred, and the resistance will be found changed as much as if the battery had been on all the time.

The incipient cohesion electrically caused can be mechanically destroyed. Sound vibrations, or any other feeble mechanical disturbances, such as scratches or taps, are well adapted to restore the contact to its original high-resistance sensitive condition. The more feeble the electrical disturbance the slighter is the corresponding mechanical stimulus needed for restoration. When working with the radiating sphere (Fig. 19) at a distance of forty yards out of window, I could not for this reason shout to my assistant, to cause him to press the key of the coil and make a spark, but I showed him a duster instead, this being a silent signal which had no disturbing effect on the coherer or tube of filings. I mention 40 yards, because that was one of the first outdoor experiments; but I should think that something more like half an mile was nearer the limit of sensitiveness. However, this is a rash statement not at present verified. At 40 yards the exciting spark could be distinctly heard, and it was interesting to watch the spot of light begin its long excursion and actually travel a distance of 2in. or 3in. before the sound arrived.

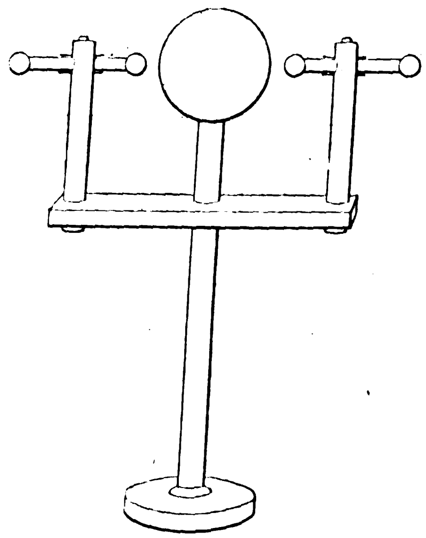

FIG. 19.—Radiator used in the library of the Royal Institution, exciting the Coherer (Fig. 18) on the lecture table in the theatre.

This experiment proved definitely enough that the efficient cause travelled quicker than sound, and disposed completely of any sceptical doubts as to the sound-waves being, perhaps, the real cause of the phenomenon.

Invariably, when the receiver is in good condition, sound or other mechanical disturbance acts one way, viz., in the direction of increasing resistance, while electrical radiation or jerks act the other way, decreasing it. While getting the receiver into condition, or when it is getting out of order, vibrations and sometimes electric discharges act irregularly, and an occasional good shaking does the filings good. . I have taken rough measurements of the resistance, by the simple process of restoring the original galvanometer deflection by adding or removing resistance coils. A half-inch tube 8in. long, of selected iron turnings, had a resistance of 2,500 ohms in the sensitive state. A feeble stimulus, caused by a distant electrophorous spark, brought it down 400 ohms. A rather stronger one reduced it by 500 and 600, while a trace of spark given to a point of the circuit itself, ran it down 1,400 ohms.

This is only to give an idea of the quantities. I have not yet done any seriously metrical experiments.

From the wall diagram which summarises the various detectors, and which were prepared a month or so ago, I see I have omitted selenium, a substance which in certain states is well known to behave to visible light as these other microphonic detectors behave to Hertz waves.

And I want to suggest that quite possibly the sensitiveness of the eye is of the same kind. As I am not a physiologist I cannot be seriously blamed for making wild and hazardous speculations in that region. I therefore wish to guess that some part of the retina is an electrical organ, say like that of some fishes, maintaining an electromotive force which is prevented from stimulating the nerves

* E. Branly, *Comptes Rendus*, Vol. CXI., p. 785; and Vol. CXII., p. 90.
† *Journal* Institution of Electrical Engineers, 1890, Vol. XIX., pp. 352-4; or "Lightning Conductors and Lightning Guards" (Whittaker), pp. 382-4.

Digitized by Google

solely by an intervening layer of badly conducting material, or of conducting material with gaps in it; but that when light falls upon the retina these gaps become more or less conducting, and the nerves are stimulated.

I do not feel clear which part is taken by the rods and cones, and which part by the pigment cells; I must not try to make the hypothesis too definite at present.

If I had to make a demonstration model of the eye on these lines, I should arrange a little battery to excite a frog's nerve and muscle preparation through a circuit completed all except a layer of filings or a single bad contact. Such an arrangement would respond to Hertz waves. Or, if I wanted actual light to act instead of grosser waves, I would use a layer of selenium.

But the bad contact and the Hertz waves are the most instructive, because we do not at present really know what the selenium is doing, any more than what the retina is doing.

And observe that (to my surprise, I confess) the rough outline of a theory of vision thus suggested is in accordance with some of the principal views of the physiologist Hering. The sensation of light is due to the electrical stimulus; the sensation of black is due to the mechanical or tapping back stimulus. Darkness is physiologically not the mere cessation of light. Both are positive sensations, and both stimuli are necessary; for until the filings are tapped back vision is persistent. In the eye model, the period of mechanical tremor should be, say, $\frac{1}{10}$th second, so as to give the right amount of persistence of impression.

No doubt in the eye the tapping back is done automatically by the tissues, so that it is always ready for a new impression, until fatigued. And by mounting an electric bell or other vibrator on the same board as a tube of filings, it is possible to arrange so that a feeble electric stimulus shall produce a feeble steady effect, a stronger stimulus a stronger effect, and so on, the tremor asserting its predominance, and bringing the spot back whenever the electric stimulus ceases.

An electric bell thus close to the tube is, perhaps, not the best vibrator; clockwork might do better, because the bell contains in itself a jerky current, which produces one effect, and a mechanical vibration, which produces an opposite effect; hence the spot of light can hardly keep still. By lessening the vibration—say, by detaching the bell from actual contact with the board, the electric jerks of the intermittent current drive the spot violently up the scale; mechanical tremor brings it down again.

You observe that the eye on this hypothesis is, in electrometer language, heterostatic. The energy of vision is supplied by the organism; the light only pulls a trigger. Whereas the organ of hearing is idiostatic. I might draw further analogies, about the effect of blows or disorder causing irregular conduction and stimulation of the galvanometer in the one instrument, of the brain cells in the other.

A handy portable exciter of electric waves is one of the ordinary hand electric gas-lighters, containing a small revolving doubler—*i.e.*, an inductive or replenishing machine. A coherer can feel a gas-lighter across a lecture theatre. Minchin often used them for stimulating his impulsion cells. I find that when held near they act a little before the spark occurs, plainly because of the little incipient sparks at the brushes or tinfoil contacts made. A Voss machine acts similarly, giving a small deflection while working up before it sparks. And notice here that our model eye has a well-defined range of vision. It cannot see waves too long for it.

(To be concluded.)

ELECTRICAL TRADES SECTION.

The members of the Electrical Trade Section of the London Chamber of Commerce met in the afternoon of Thursday, June 7th, at the offices, Botolph House, Eastcheap, under the presidency of Major Flood Page.

After the usual preliminaries were disposed of, the Chairman said that the members would remember that when they did him the honour of appointing him to the chair he accepted the office on condition that the appointment should be for only two years. The subject was discussed pretty freely at the time, and they came to the conclusion that it would be far better that they should have a change of Chairman every two years. For that period he had presided over the Section, and he now took the opportunity of thanking them for the kindness and forbearance with which they had treated him during the time he had held that honourable position. He had been, more or less, in bad health the whole time, and had not been so active, perhaps, as he might otherwise have been. He believed that it now became his privilege to nominate his successor, and he had great pleasure in proposing that Mr. Emile Garcke should be elected to the office.

Mr. Sellon seconded the motion, which was agreed to unanimously.

Mr. Garcke, having taken the chair, said that while thanking them for the confidence which they reposed in him by placing him in that responsible position, he felt that he occupied it under the great disadvantage of its having been filled first by Mr. Crompton and then by Major Flood Page. He could but say that he would do his best to perform his duties to the satisfaction of the members. He would like to refer to the very valuable services rendered to the Section by Major Flood Page during his period of office, and to propose a vote of thanks to him for his services. Although that gentleman had not enjoyed the best of health, they must all recognise that he had devoted a great deal of time to the interests of the Section, with the result that they had been enabled to carry out some very important business matters in which they were all interested, such as the subject of overhead wires and various other questions which had to go before the Board of Trade, in connection with which Major Flood Page had rendered very valuable service.

A Member briefly seconded the motion, which was cordially passed.

Major Flood Page, in expressing his acknowledgment, said that he would be still able to be of some little use to the Section, because the Council had done him the honour of electing him to be a permanent member of that body, and, therefore, in addition to the fact that Mr. Garcke, as Chairman of the Section, would be entitled to attend the meetings of the Council, he (Major Flood Page) would always be there to act upon any suggestion which Mr. Garcke might recommend.

On the motion of the Chairman, seconded by Mr. Sydney Morse, Mr. Siemens was elected Deputy-Chairman.

After a short discussion, a committee was formed to watch the interests of the Section in connection with the rating of electrical works, and a letter was read on the subject of the Locomotive Acts from the Board of Trade, intimating that the representations of the Section on the question of their amendment had been brought to the notice of the Home Office.

The consideration of the provisions of the Electric Lighting Acts with regard to alleged nuisances was left in the hands of the same committee.

On the suggestion of the Chairman, seconded by Mr. Morse, and supported by Mr. Sellon, it was decided to circularise the various departments of the electrical industry, urging upon them the desirability of supporting the Section in promoting the interests appertaining to each.

The proceedings then ended.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

New York, *June* 2, 1894.

New Telephone Rates.—The local New York City Telephone Company on June 1st introduced a new system of charges for telephone service, based upon the number of messages sent by a subscriber. All lines will be metallic circuits, and the subscriber sending messages of not less than 1,000, nor over 2,000 annually, may elect if he will have a line for his sole use, or share one with another subscriber. The lowest annual rate, $100, is for "two-party" lines only and 700 messages, the charge for additional messages being $15 per 100. The lowest rate for a "direct" line is $150 per annum, 1,000 messages being the limit; the charge for those in excess of that number being $12 per 100. A "two-party" line for this service costs $20 less per annum. For 2,000 messages per annum the charge for a "direct" line is $220, and for a "two-party" line $200; excess messages being $8 per 100. For more than $2,000 messages "direct" lines only can be used, and the rate will be $5 per 100, with $7 per 100 for excess messages.

Central Stations in Massachusetts.—A recent report of the Board of the Gas and Electric Light Commissioners of the Commonwealth of Massachusetts for 1893, shows that, during the last year, out of 60 central electric lighting stations in that State 28 paid dividends, 26 paid no dividends, and 6 did not earn expenses. Of the $434,328 paid in dividends, two Boston stations paid $257,808, and the several larger cities paid the greater part of the remainder. Five stations, including those of Boston, paid 8 per cent., two 7 per cent., ten 6 per cent., and two 5 per cent. The assets of the various companies were returned at $14,275,363.23; 37 showing a surplus of $671,261.16, and 23 a deficit of $116,848.15. The

Digitized by Google

assessed value of the plants for taxing purposes is $4,588,067, corresponding to a real value in the neighbourhood of $6,000,000. The dynamo capacity of the stations is 293,000 16-c.p. incandescent lamps, 9,910 2,000-c.p. and 9,121 1,200-c.p. arcs. 341 motors are supplied from incandescent circuits, 530 from power circuits, and 30 from arc circuits; the aggregate horse-power being 6,843.

CORRESPONDENCE.

WRIGHT'S DEMAND INDICATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The description of Mr. Wright's Demand Indicator and the account of its effect on the load diagram of the Brighton Corporation, in your issue of June 1st, is most interesting. These instruments have, I understand, been in use at Brighton for over a year, and have been the means of procuring valuable information as to the actual distribution of the load. But it would be interesting to know how they have been appreciated from the consumer's point of view. What innumerable arguments and explanations must have taken place between the Corporation's officials and the consumers. If the majority of the Brighton consumers consisted of professors and amateur electricians, I could believe that matters have worked comparatively smoothly; but what does the average shopman think of these complicated methods of charging for the supply? My experience, both in London and the provinces, with less complicated methods of charging has not been such as to lead me to believe that the ordinary consumer will look upon the demand indicator as an unmitigated blessing. The consumer wants to know nothing about load factors and how he can assist the supply company. What he wants is to get his supply at as low a price as possible per unit, and he does not want to be told that he should be careful to ask if the lights are switched off in the dining-room before he switches on those in the drawing-room. He considers that he had the electric light laid on in his house for his own convenience, and to use exactly as he likes and when he likes. The idea of his having to give 24 hours' notice to the Corporation that he wishes to switch on an extra number of lamps for a particular night, as otherwise his account for the whole month will show a serious increase, may appear very simple, but in actual practice the annoyance and trouble both to the consumer and to the Corporation would certainly be a very great objection. The electric light companies which are on the best terms with their customers are those who make it a rule to have the least to do with them. Consumers object to frequent visits of the supply company's officials; a monthly call of the meter inspector is as much as most of them will stand.

Some customers have a firm conviction that electric lighting companies are great monopolies, which were formed with the express object of swindling the public. The humble meter reader is looked upon as the wicked agent of the company, who will stick on a few extra units if he only gets the chance. These people like to be able to calculate the amount actually used at certain times in pounds, shillings, and pence. For this reason they like to have meters which read direct in Board of Trade units, as a constant multiplier with decimals is too much for them. What would these people have to say to the demand indicator and the Brighton system of charge?

It may be said that the demand indicator was not worked out on the assumption that all consumers are devoid of ordinary intelligence. I do not in the least insinuate anything of the sort. What I say is, that the average consumer does not like a complicated system of charging; he can easily understand the charges of the gas company, and he does not see why the account for electric light should not be equally simple. I assume that there is not much difference between the London customers and those of the Brighton Corporation, and I think I know the species fairly well.

The increased clerical work which must be necessary in getting out the accounts on this system of charge must be by no means a negligible quantity.

The instrument and the system are a credit to the inventor's ingenuity, but surely they are more suitable for use in connection with small plants, with a limited number of consumers, than on a system of such large dimensions as that which the Brighton Corporation's promises to assume under Mr. Wright's able management?—Yours, &c., PERCY STILL.

Draycott-place, Cadogan-gardens, S.W.,
June 9, 1894.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As you have kindly favoured me with Mr. Still's remarks on my method of charging for electricity, it may be well to point out to him that the primary use of my instrument is to make the reduction of charge for electricity consumed depend on the actual use the consumer has made of the plant and mains laid down ready for him, and not necessarily on his intelligent appreciation of the equitable nature of the method of charge as Mr. Still seems to suppose. The subject is essentially a commercial one of how equitably and profitably to charge, as low rates as possible for electricity, and I therefore fail to see why it should be only understood by amateur electricians. It is not a matter of importance from a central station point of view whether the consumers understand the theoretical basis of the system or not; but every consumer appreciates a reduced charge, and our customers have no difficulty in understanding that the longer they burn their lights the cheaper the rate at which they will be charged for it. We cannot say whether, theoretically, our customers understand the system; but it will interest Mr. Still to learn that during the past year we have not experienced that abundance of argument from our customers that he anticipates, and the fact remains that they have taken advantage of the inducements we held out to them by lengthening their demand and improving the load factor at the central station 15 per cent., and this without any special instructions other than those shown on the indicator itself and a circular announcing the reduction. Mr. Still will probably fully appreciate an improved load factor in these days of shrinkage of earnings per lamp, as it clearly shows the method is a commercial success. Our customers can take their light how, when, and in what manner they please, and in any case they pay no more than they did before the reduction was inaugurated; but we offer a consumer every inducement to effect his own reductions by thoroughly wiring his premises, as in the ordinary course of things no one uses all their rooms or premises at one time, and your correspondent is hardly justified in assuming that a man will wantonly leave electric lights burning in empty rooms any more than that the same man at present recklessly wastes his gas in a similar way.

I noticed the average number of units consumed per lamp installed of the Company Mr. Still is connected with have fallen from 12·5 to 10·3, while ours in Brighton have risen from 19·5 to 22, and I venture to say the principal reason for this great difference is probably because in Brighton we encourage, by reducing the charges, the use of the light in basements, and long-used rooms. Mr. Still may probably reply that the reason of the small and decreasing earnings per lamp in Chelsea is because their new customers are largely composed of private houses, which have the light installed in the reception and best bedrooms only, while the basements, kitchens, passages, and other dark places requiring constant light are gas-lit, because gas is cheaper than electricity at 8d.; it is thus shown that the very places that electricity is most needed, and would be most used if charged at sufficiently low rate, have to go gas-lit, but on our system they would be the cause of effecting good reductions on the whole bill by increasing the average quantity consumed per lamp used. It must be borne in mind that those who are responsible for the financial success of electric lighting, must look at the manner of charging from the central-station point of view, and it is imperative for reductions to be equitable, that customers should benefit in the exact ratio to their profitableness.

Our system can claim all this, and by it we can afford to give larger reductions to the most profitable customers, whether large or small consumers, than by any other method. Again, his opinion regarding short circuiting, the demand indicator on

Digitized by Google

special occasion being a source of annoyance to the consumer, overlooks the fact that it is only done at the request and for the benefit of the consumer; he is also unaware that the instruments are direct reading, and do all the necessary accountants' work themselves, as the scale used on each instrument dispenses with extra clerical work, and the clerks prepare the bills showing a certain number of units at 7d. and a certain number at 3½d.; and Mr. Still will be interested to learn that we have no difficulty in this respect.—Yours, &c., ARTHUR WRIGHT.

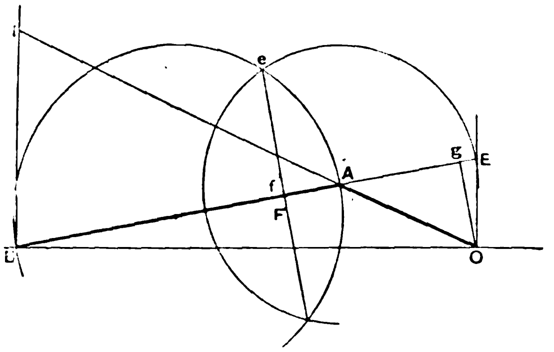
The Brighton Corporation Electricity Works,
North-road, June 13, 1894.

INERTIA OF THE RECIPROCATING PARTS OF A STEAM ENGINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The very simple graphical construction of Prof. J. F. Klein, Lehigh University, for the determination of the acceleration of the piston of a steam engine seems to be little known on this side of the Atlantic, as several new text-books have appeared since its publication (*Journal* of the Franklin Institute, September, 1891), in which the analytical treatment of the subject is given, or the less simple graphic method of Ritterhaus.

The following is Klein's construction:—Let O A and A B be the crank and connecting rod in any position, let the lengths of the crank and connecting rod be r and l respectively. Produce the connecting rod B A to cut the perpendicular O E to the line of stroke. With A as centre, and A E as radius, draw a circle; on A B as diameter draw another circle, and let the common chord of the two circles cut the line of stroke in F. Then F O is the acceleration of the cross-head to the same scale as O A represents the centripetal acceleration of the crank pin.



The demonstration is as follows:—The motion of the cross-head B may be compounded of two motions: (*a*) a motion of constant velocity, V, in the crank-pin circle; (*b*) a motion of rotation about A, with angular velocity $\frac{V}{AI}$. The acceleration due to the motion (*a*) is $\frac{V^2}{r}$, and is in the direction A O. If the scale of velocity be chosen so that V is represented by the length A O, the acceleration $\frac{V^2}{r}$ may also be conveniently represented by A O; the component of this acceleration in the direction of the connecting rod will then be Ag (Og being drawn perpendicular to A E). The radial acceleration due to the motion (*b*) is $\frac{V^2}{AI^2}l$, and, making the same assumption as to scale, will be represented by the length $\frac{AE^2}{AB} = fA$ (since $\frac{fA}{Ae} = \frac{Ae}{AB}$). The tangential acceleration due to (*b*) has no component in the direction A B. Adding, the component of B's acceleration in the direction B A is fg. But obviously the total acceleration of B is in the direction B O, and must therefore be equal to F O, since fg is the component of F O in the direction B A.

If an ordinate be drawn from B of length equal to F O, and the construction repeated for a number of different crank-pin positions, the rectangular curve of piston acceleration is obtained.

Klein's construction does not fail (as Ritterhaus's does) at the dead points.

If w be the weight of the reciprocating parts per square inch of piston area, and f be the acceleration, the steam pressure in pounds per square inch required to accelerate the moving parts is $\frac{wf}{g}$.—Yours, &c., ARCHD. SHARP.

Guilds Central Technical College,
May 31, 1894.

LEGAL INTELLIGENCE.

Sellman v. Brasyer and Another.

In an action brought before Mr. Justice Mathew by Mr. Sellman, an "electro-masseur," against Col. Brasyer and Mr. F. T. Burbage to recover damages for an alleged malicious prosecution in the recent Medical Battery Company action. Col. Brasyer denied that he preferred any charge, and both defendants pleaded reasonable and probable cause. In 1884 plaintiff was a vocalist, and adopted the professional name of Dudley Towers. In 1886 he was introduced to Harness, and subsequently sang at some concerts given at 52, Oxford-street. Harness told him that he would make him a permanent member of the staff if he would study for an "electro-masseur," and, accordingly, he became a pupil of Dr. Stretch Dowse, and at the expiration of six months received a certificate, and was engaged by Harness as a masseur at a salary of £1 a week. He received an additional commission of 2½ per cent., when patients had a second course of treatment. He had a room in the saloon which was fitted up with batteries and other means of applying electro-massage. He was never known at the Oxford-street establishment as Dr. Towers. Mr. Burbage was a patient, and after reading his testimonials, in which references were made to presents, said if the plaintiff cured him he would give him a present of a box of cigars, which he subsequently did. The plaintiff left the services of the Medical Battery Company in January, 1893, and since that date had had nothing to do with the Company or its business. After leaving the Company he started business on his own account as a masseur, and subsequently at present address. His business increased rapidly, and at the time of his arrest his income varied from £10 to £15 per week. On the evening of November 15, 1893, he went out to post a letter, when he was arrested in the street on a warrant charging him with conspiring with others to defraud the individuals named in the warrant. After this charge against him had been withdrawn he gave evidence. He never told Mr. Pitman, nor Mr. Harvey, nor Mr. Collier, the solicitor, that Mr. Harness deserved five years, or that he was a rogue. He knew nothing about Mr. Harness's character. Plaintiff denied that Mr. Harness was paying the expenses of this action. He had given a bill of sale on his furniture to enable him to clear his character of this wretched stain. The plaintiff's wife also gave evidence, and said she was a saleswoman with Harness six or seven years. After hearing counsel on both sides, the Judge summed up, but the jury were unable to agree to a verdict, and were discharged.

Newgas and Co. v. The Gulcher (New) Electric Light Company.

On Tuesday Mr. Justice NORTH made an order in a debenture holders' action for the appointment of a receiver of the property of the defendant Company.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Corporation of Cheltenham invite tenders for the supply and delivery of electric lighting cables. Copies of specification and forms of tender may be obtained from Mr. Joseph Hall, the borough engineer, and tenders must be delivered to Mr. E. T. Brydges, the Town Clerk, not later than noon on the 19th inst. Some further particulars appear in our advertisement columns.

———— The Cheltenham Corporation also require tenders for the erection of a central electric lighting station. All particulars can be obtained of the Borough Engineer, and tenders have to be in to Mr. E. T. Brydges, town clerk, Municipal Offices, Cheltenham, by noon of the 19th inst.

———— The Electric Lighting Committee of the Blackpool Corporation invite tenders for boiler-seatings and flues, engine and dynamo foundations, &c. Further particulars can be obtained from Mr. John Hesketh, the Borough Electrical Engineer, Electricity Works, Blackpool.

———— The Corporation of Kingston-upon-Thames require tenders for the supply of a gas or oil engine, for their electric light station, which tenders must be sent in by the 20th inst. Particulars can be obtained of Mr. A. H. Preece, 39, Victoria-street, Westminster, S.W.

Digitized by Google

TENDERS INVITED.—The Vestry of St. Pancras (London) invite tenders for the buildings required at the electric lighting and refuse destructor station in King's-road, Camden Town, N.W. Drawings, &c., can be inspected and specifications obtained at the offices of Prof. H. Robinson, C.E., 13, Victoria-street, Westminster, and tenders must be sent in to Mr. A. E. Pycraft, chief clerk, Electricity and Public Lighting Department, Vestry Hall, Pancras-road, N.W., by noon of the 18th inst.

TENDERS ACCEPTED.—The following tenders have been received by the Paddington Board of Guardians for the electric lighting of the female wards of the Paddington Infirmary, to the specification of Mr. A. W. Sclater, Assoc.M.Inst.C.E. :—

	£	s.		£	s.
J. E. Spagnoletti & Crookes (accepted)	101	13	D. Bate	156	0
New and Mayne	107	0	Newton and Co.	159	0
Sotheby and Ridout	109	10	Henry F. Joel and Co.	159	9
Pritchett and Gold	122	10	Strode and Co.	167	0
Wenham and Waters	122	10	Girdlestone and Tatham	173	15
Peto and Radford	125	0	Vaughan and Brown	174	0
Jarvis and Berry	128	10	F. Geere Howard	175	0
Roger Dawson	132	0	Walter, Andreae & Co.	175	0
Dawson, Hammond & Co.	135	0	W. Mackie	176	0
Russell and Co.	139	0	Laing, Wharton and Down	182	11
D. Hulett and Co.	142	15	E. P. Allam and Co.	184	5
Crompton and Co.	143	0	Harrison, Coles and Co.	210	0
Lund Bros.	146	0	Peter Jones	214	0
J. W. Carpenter	146	13	Benham and Sons	235	0
Fenton and Barnes	153	0	H. Thorpe	284	15

——— For the generating plant required at the works of Messrs. C. H. Glover and Co., of Hatcham, S.E., the tender of Messrs. J. G. Statter and Co. has been accepted.

——— The tender of Messrs. W. Gradwell and Co., of Barrow-in-Furness, has been accepted by the Newport (Mon.) Corporation for the erection of an electric lighting station.

TENDERS RECEIVED.—The London County Council have received six tenders for the gas engines required for the proposed pumping station at Nine Elms Lane :—

Robey and Co., Lincoln	£4,079
J. E. H. Andrew and Co., Stockport	3,550
Fielding and Platt, Gloucester	3,500
Dick Kerr and Co., London	3,045
Tangyes, Birmingham	3,006
Crossley Bros., Openshaw, Manchester	2,724

LIQUIDATIONS.—A petition has been presented for the compulsory winding up of the Collier Audible Telephone Syndicate (Limited), and is down for hearing at the Royal Courts of Justice, Strand, on June 21st.

——— At a meeting of the Lithanode and General Electric Company (Limited), held on June 5th, it was resolved that the Company be voluntarily wound up, and Mr. J. H. Hays, 11, Abchurch-lane, E.C., was appointed liquidator. We learn that it is probable an attempt at reconstruction will shortly be made.

——— Claims against Roper's Electrical Engineering Company, Limited (in voluntary liquidation), must be sent to Messrs. Neill and Holland, solicitors, Bradford, by July 20th.

APPOINTMENT.—Mr. R. R. Binnie, chief engineer to the London County Council, has been appointed county surveyor to the same body. Mr. Binnie had previously performed the duties of the office without having been formally appointed.

VACANT APPOINTMENTS.—The Committee of Management of the Municipal Technical School, Brighton, require an assistant lecturer in mechanical engineering, &c., salary £150 per annum ; an assistant lecturer and instructor in electrotechnology, salary £20 per session ; and an engineering workshop mechanic, salary £95 per annum. Further particulars can be obtained from Mr. F. J. Tillstone, town clerk, the Town Hall, Brighton, to whom applications must be sent in before 10 a.m., 18th inst.

REMOVAL NOTICE.—Mr. William Kingsland, A.I.E.E., has removed from Clarence-buildings to 139, Upper Mostyn-street, Llandudno. We are informed that Messrs. Kingsland and Bellis are pushing on with their scheme for lighting Llandudno, notwithstanding the recent decision of the Local Board. It is stated that a strong directorate has been formed, and that the Llandudno Electric Supply Company (Limited) will be registered in a few days.

RE WOODHOUSE AND RAWSON UNITED (LIMITED).—It is announced that, on the application of the Official Receiver, Lord Aberdare, Sir R. W. Rawson, Sir John Stokes, Samuel Pope, Q.C., F. L. Rawson, W. T. Stutchbury, A. Hoster, T. H. Lambert, C. L. Baker, A. L. Foley, J. H. O. M. Dundas, Mr. Mumford, Philip Rawson, and F. W. Pixley are to attend to be publicly examined before one of the Registrars in Bankruptcy, at the Bankruptcy Buildings, Carey-street, London, W.C., on the 18th, 19th, and 20th inst., at 11 a.m.

MESSRS. FARADAY AND SON.—This firm inform us that the leases of adjoining premises having been acquired, the area of their show-rooms has been more than doubled, and the workshops greatly enlarged and new plant put down. The increased room has enabled them to add new departments to the business.

MR. WILSON HARTNELL.—Amongst the contracts recently obtained by this firm, and which have either been just completed or are in hand, is the electric lighting installation for the Leeds County Liberal Club, the plant for which includes two 12,000-watt Hartnell dynamos of the latest type, driven by two Crossley gas engines. The plant for the lighting of two corn mills, one at Stockport and one near London, are also in hand, in addition to several large dynamos and patent governors for electric light engines.

NEW FIRM.—Messrs. J. Fecher and Co., manufacturers at Bavaria of electrical porcelain work, have opened offices and show rooms at 11, Idol-lane, Great Tower-street, E.C., where a stock of their specialities will be kept.

PHOTOGRAPHIC APPARATUS.—Mr. C. C. Vevers, of 12 and 12A, Market-street, Briggate, Leeds, has sent us an illustrated catalogue of photographic apparatus, materials and chemicals, together with a scale of charges for trade printing, enlarging, finishing, &c.

ACTON.—The Acton Local Board have agreed that the district shall be supplied with the telephone, provided 900 subscribers are willing to come forward to meet the necessary expenditure.

AVILA (SPAIN).—A correspondent describes an interesting ceremony which took place at Avila a short time back at the opening of the electric lighting station on the Sunday. At four o'clock a procession appeared, headed by the Bishop of the diocese, who came down to bless the installation and open the works. The appearance of the Bishop was the signal for a flight of rockets, after which the Bishop walked to the boiler-house, where he delivered a short prayer, and sprinkled the two Babcock-Wilcox boilers with holy water. The engines and dynamos were similarly treated, much to the dismay of the engineer. Fortunately only a few drops fell, and no harm was done. The Bishop subsequently delivered an eloquent sermon on the advantages of modern science as given to the people. About 2,000 persons were present.

ANTWERP EXHIBITION.—This exhibition is now nearly completed, and by the end of the month the Machinery Hall will contain the whole of the exhibits intended to be shown. Very few English firms are exhibiting, but notwithstanding this, the electrical and engineering exhibits are, many of them, extensive and complete. Messrs. Crompton and Co. have a good show, as have many of the well-known Belgian, French, and German houses. The British section is particularly weak, excepting in the display of models of ships built for British and foreign Governments and for the leading steamship lines. These models are especially fine, and attract much attention. Notwithstanding the bad weather of the past fortnight, the Exhibition has been fairly well attended, thanks largely to the interest taken in the progess of the work by the King of the Belgians. Novelties are rare, but many of the stands show conspicuous ability on the part of those responsible for their construction. The popular side-shows are numerous, and are likely to attract large crowds as soon as the weather adapts itself to outdoor amusements. The London, Chatham, and Dover Railway Company are issuing cheap tickets, available for 30 days, *viâ* Queenborough-Flushing by the boats of the Zeeland Steamship Company, which are the largest passenger boats plying between Great Britain and the Continent.

AYR.—At the last meeting of the Town Council a letter was received from the Ayr Harbour Trustees, asking what charge would be made for supplying eight 3,000-c.p. arcs for the north side of the river and dock, and four for the south side. It was agreed to supply these lamps at the rate of 4d. per unit, the trustees providing lamps and requisite plant.

BARNET.—The Electric Lighting Committee of the Local Board have reported on the result of their endeavours to obtain the views of the ratepayers on the electric lighting question. A circular had been issued, and a house-to-house visitation made, with a more or less satisfactory result. Many of the ratepayers recommended that the matter should be postponed until the election of the District Council, the question being a test one at the election. There was general agreement as to the badness of the gas supplied to the district and its high price. A letter was read from the Brush Company, and also a communication from Messrs. Crompton and Co. The latter firm stated that they would be quite prepared to accept the general principle of undertaking the risk for a period of years, supplying the light without any guarantee, the local authority finding the necessary capital. It was ultimately decided that the Board should discuss the matter with Messrs. Crompton on the basis of the necessary capital being found by the Board, other matters being left open for consideration.

BARROW.—At the last meeting of the County Council, the Clerk announced that the Board of Trade had granted the Electric Lighting Provisional Order.

CANTERBURY.—A public meeting is shortly to be held to consider a proposal for raising the necessary capital of the Canterbury Electricity Supply Company (Limited).

CARDIFF.—The Borough Engineer has been requested to report on the advisability of extending the electric light to the Market Hall and Town Hall. The Electric Lighting Committee have asked Mr. W. H. Massey and the Borough Engineer to prepare a pamphlet upon the subject of the electric light for distribution throughout the town.

CHESTER.—The dispute as to the site to be selected for the electric lighting station has now been settled by a vote of the Town Council, which has rescinded a former resolution adopting the Hop Pole site. A new site will now have to be selected.

CHISWICK (LONDON).—The plans sent in by Messrs. Bourne and Grant, who hold the Provisional Order for lighting the Chiswick district by electricity, of the proposed buildings and engines for the generating station have been referred to a committee for consideration and report.

COLCHESTER.—The Lighting Committee of the Corporation have received a report from Mr. W. H. Massey as to the advisability of the Corporation undertaking the supply of the electric light, which has now been submitted the same to the Councillors. Mr. Massey says that he is still of the opinion expressed by him some years ago that electric lighting in Colchester cannot be carried on at a profit by a company, but he thinks that the Corporation may be able to run electric lighting works with advantage. He has inspected several suggested sites for a central station, and suggests that a piece of land between the milk factory and the Corporation-yard is the best, as there it would be possible to arrange for electric light works side by side with apparatus for burning refuse. Mr. Massey estimates the total initial expenditure at about £18,000, and recommends, if the above site is selected, the low-tension three-wire system. The Lighting Committee are considering the report, and will probably make a recommendation to the Council at the next meeting.

CHURCH AND CHAPEL LIGHTING.—At Castle-gate, Nottingham, the Congregationalist chapel is to be lighted by electricity. The chapel is undergoing complete renovation, and the opportunity is being taken to instal the electric light.

DERBY.—The Baths Committee of the Town Council recommended in their report to defer for the present the consideration of the question of lighting the Full-street Baths by electricity, but as this was objected to by Mr. Marsden, it is probable that the matter will receive the immediate attention of the Council. Owing to the interest taken in the electrical exhibition, a much wider interest in the public electric lighting scheme has been created. Visits have been made from several of the Midlands' Engineering and Colliery Managers' Associations, and Mr. Stewart, the manager of the electric lighting works has been busy conducting demonstrations and in describing the machinery at the works in Full-street.

DUBLIN.—The Corporation are extending the electric lighting area from Cavendish-row and Rutland-square in continuation from the Rotunda in Upper Sackville-street.

EALING.—A request made by Dr. Scott to the Local Board for permission to lay telephone wires in the trenches in which the electric light mains are laid was refused at the last meeting of the Board.

ECCLES.—The Electric Lighting Committee have received a report from Dr. J. Hopkinson on the electric lighting scheme, and also a letter stating that with respect to the names of places at which the street lamps were lighted by electricity, Whitehaven was the only place he knew of in this country wholly thus lighted. The Council agreed that the Committee should inspect the lighting of the Whitehaven streets, with the view of obtaining information to enable them to report fully on the subject. We understand, however, that Prescot has been similarly lighted by the British Insulated Wire Company.

ELECTRIC LIGHT IN GREENHOUSES.—In a recent report published by the authorities of Cornell University, Prof. Bailey states that for four winters study has been made of the influence of the electric arc lamp upon plants grown in greenhouses under varying conditions. It was found that lettuce was greatly hastened in growth by the electric light, and various flowers were earlier and better under its influence. Many plants were injured by the naked electric light, but sustained no injury by a light which was modified by passing through an opal globe, or even through common glass. Radishes and other plants injured by the naked light in the greenhouse, and even by the light modified by an opal globe, were benefited by a light above the roof, and lettuce and flowers still showed a marked benefit from this arrangement. Other experiments have been made, and a series of bulletins have been issued (Nos. 30 and 42).

FAREHAM.—From the *Hampshire Evening Mail*:—"We are sorry to hear that the Fareham Electric Lighting Company is about to collapse, but the townspeople having said pretty plainly that they would have nothing to do with it as a public undertaking the demise is inevitable. The concern has had a brief career of four years, and the reason for its failure is the insufficiency of public and private support. It was started with a capital of £5,000, and with this a fairly satisfactory system of lighting was started, but the overhead wires have been a constant cause of contention, and now that the Board of Trade insist on the cables being placed underground the Company want capital, and cannot obtain it. Under these circumstances it is impossible to go on, and it now rests with the Local Board to say whether they can and will come to the rescue."

FLEETWOOD.—The Board of Trade have fixed October 20th as the limit of time for work to be commenced under the Fleetwood Electric Lighting Order of 1890.

GLASGOW.—Mr. W. Lackie, Electrical Inspector to the Corporation, is of opinion that no ventilating system is requisite in electrical conduits. Although there are nearly 500 manholes in Glasgow, only in six has any trace of gas been discovered, and this has been caused by the railway operations which have been conducted throughout the city.

HARTLEPOOL.—At the last monthly meeting of the Town Council the Lighting Committee's report was brought up for discussion; and Mr. Foxton called attention to the necessity for the Council securing powers for electric lighting before they were acquired by the Tramways Company. In reply, Mr. Watson said that the matter had been allowed to rest pending further information, as it had been discovered that the cost of obtaining powers amounted to nearly £300.

ISLINGTON (LONDON).—The thirty-seventh annual report of the Islington Vestry, recently published, contains a history of the electric lighting question, and sets out the progressive steps taken from time to time to bring the Vestry's electric lighting scheme into practical working.

LAUNCESTON.—The Town Council have received an offer from the Western Electric Company to purchase the existing waterworks for electric lighting purposes. The letter came up for discussion at the last meeting of the Council, but no action was taken.

LLANBERIS.—A survey is being made by Mr. A. Smith, with the view of constructing an electric railway to the summit of Snowdon. The tourist traffic from the Llanberis side has recently fallen off, owing, it is stated, to the counter attractions from the Beddgelert route.

LYNTON.—It is stated this is the only town in the kingdom where the ancient and modern lights, oil lamps and electricity, may be seen burning at the same time. Gas is unknown at Lynton.

MAIDSTONE.—In answer to a question from Alderman Long at the last meeting of the Local Board as to the position of affairs with regard to the Electric Lighting Order, which expires in a few weeks, it was stated that the Board were awaiting a reply from a London company.

MILL LIGHTING.—In reference to the Trade Note in our last issue under this heading, Mr. Wilson Hartnell wishes us to state that the plant at Messrs. Fletcher's mill at Milford, near Belper, was put down by him, and has been running for more than a month with every satisfaction.

MONTROSE.—Mr. C. L. Hett writes to say that in the description of the lighting of Kinnaber waterworks in our last issue we omitted to mention that the Pelton water-wheel, from which the motive power is derived, was constructed by Mr. Hett, and is fitted with the Hett patent adjustible nozzle.——The Scottish House-to-House Company have intimated their intention to apply to the Board of Trade for a Provisional Order to supply electricity within the borough of Montrose, and have asked the consent of the Town Council to their application. A motion was proposed that before entering into any negotiations the Lighting Committee should ascertain the terms upon which the electric light undertaking could be carried out in Montrose, either under a Provisional Order obtained by the Council or by a company. This was agreed to. Notice was given that at the next meeting Mr. Whiteman would move that the Council themselves apply for a Provisional Order to supply electricity within the district.

NEWCASTLE.—The Corporation has published in pamphlet form the report prepared by Mr. W. G. Laws, the city engineer, on "Three Systems of Tramway Haulage," horse, electric, and cable. The City engineer has also presented a report as to the estimated cost of renovating the Town Hall, installing the electric light, &c., which is to cost about £3,000. The Corporation have voted £200 to the Special Committee which is considering the subject of a municipal electric lighting scheme.

NEWPORT (MON.).—The Corporation have decided to make the following charges for electric current:—Under 1,000 units, per quarter, 6d.; above 1,000 and under 2,000, 5½d.; above 2,000, 5d. It has also been decided that all Corporate buildings, including the

Digitized by Google

Town Hall, free library, markets, baths, slaughter-houses, &c., are to be lighted by electricity.

"PALL MALL BUDGET."—It has been decided to start a new series of this popular weekly, increased in size and containing many novel features. The *Budget* is associated with the *Pall Mall Gazette* establishment, and has become a public favourite.

PROVISIONAL ORDERS.—The House of Commons Committee on Local Bills have approved the Grimsby Electric Lighting Provisional Order No. 2 Bill, and ordered it for third reading.——The Plymouth Electric Lighting Provisional Order has been read a third time, and confirms a Provisional Order made by the Board of Trade applying to the Saint Austell district.——The Monmouth Electric Lighting Provisional Order has passed the House of Lords Committee, and is reported for second reading.

RADCLIFFE.—A meeting of the Local Board has been held, at which a discussion took place on the question of applying for a Provisional Order for lighting the district by electricity. Mr. Cuncliffe argued strongly in favour of the Board taking up the subject, and pointed out that they had already experts from whom they had received favourable reports, and finally moved that the Board should take the necessary steps for obtaining a Provisional Order. The motion was agreed to.

RURAL TRAMROADS.—It is stated that experimental electric railtracks, so constructed that ordinary vehicles as well as electric cars can be used upon them conveniently, are about to be laid on some of the country roads in Ohio, U.S.A.

SHOREDITCH (LONDON).—In further discussing the Vestry's scheme for combining dust destruction, baths and washhouses, and the construction of an electric lighting station on the Pitfield-street site, after a heated debate on Tuesday last it was decided to purchase the property referred to for the sum of £33,500. This matter has been before the Vestry for the past eighteen months, and has been discussed on various occasions without any definite result being arrived at. The Pitfield-street site is in the centre of a densely-populated district, and it remains to be seen whether the decision arrived at by the members of the Vestry is a wise one. The voting was very close, 32 being in favour of the purchase of the site and 29 against. The opposition chiefly centred in the unsuitability of the site for the purposes of the scheme.

SOUTHAMPTON.—At the last meeting of the Town Council, the Works Committee reported that the town clerk had been instructed to inquire of the local electric lighting company the terms upon which they were prepared to enter into negotiations for the sale of their undertaking to the Corporation.

SOUTHPORT.—A report of the Gas and Electricity Committee submitted to the last meeting of the Corporation contained several references to the differences of opinion existing between the Committee and the Corporation's electrical engineer, on the question of foundation plans for engines, dynamos, and boilers. The town clerk reported that in his opinion the electrical engineer had become incapacitated within the meaning of Clause 18 of the agreement entered into between him and the Corporation, and it was resolved that the Committee hear with regret of the indisposition of Mr. Wilkinson, and instruct the town clerk to effect a friendly arrangement for a legal discharge from all liabilities under the agreement.

ST. LUKE'S (LONDON).—The Vestry having received from the County of London and Brush Provincial Electric Lighting Company an undertaking not to offer any opposition to the Vestry's application at any future date for a Provisional Order, have notified the Board of Trade that they have no objection to offer to the Company carrying out the work of lighting the parish.

ST. PANCRAS (LONDON).—Mr. A. Sweet, the Chairman of the Electricity Committee of the Vestry, presented the annual report at the last meeting of the Vestry. The report shows a satisfactory result on the year's working. The total income was £15,002, which is sufficient to clear off a deficit of £1,543 for the first year's working, and after paying all working expenses and £927 in maintaining the works in the highest state of efficiency, leaves a balance of £4,669, out of which interest and repayment of loans has been met. The extension of the Stanhope-street station, which is now nearing completion, and the provision of a new station in King's-road will, it is anticipated be in working order, and available for the next winter supply. The report states that the ratio of cost of public lighting for the year by electricity as compared with gas was high, but the charge of 6d. per unit is to be reduced to 5d. per unit (as previously announced) from Michaelmas next. The report further states that the supply of current for private lighting, although not large, is promising, and the number of private consumers has doubled during the past year. The report was adopted.——A letter was subsequently read from the Gas Light and Coke Company announcing that from the end of the current quarter the price of gas for public lighting is to be increased from 2s. 2d. to 2s. 4d. per 1,000. The amount paid by the Vestry to the gas company for the year ended March 25th last upon the basis of 2s. 2d. per 1,000, was £8,788, and the increased price would add to this sum no less than £676. The Vestry, after discussing the letter from the Company, passed a resolution emphatically protesting against the increase, and Mr. Sweet, the Chairman of the Public Lighting Committee, recommended the Vestry to checkmate the Company by lighting all the main streets of the district by electricity, which it will shortly be in a position to do.

STRAND (LONDON).—At the last meeting of the Strand Board of Works a special report was presented from the Works Committee respecting a memorial from the Charing Cross and Strand Electricity Supply Corporation proposing to supply the electric current to the parish of St. Paul's, Covent Garden, at £26 per 2,000-c.p. arc lamp, for 10 hours per day, this sum to include maintenance, lighting, and supply. The Committee reported that if competitive powers were granted to a second company they should apply to the whole district, and not to one parish, and this opinion of the Committee was endorsed by the Board.

SUNDERLAND.—Fifty-nine applications were received by Prof. Kennedy for the position of Electrical Engineer to the Sunderland Corporation at a salary of £200 per annum. Acting on the instructions of the Committee, this large number had been reduced to seven, and of these Prof. Kennedy specially recommended Mr. C. S. Vesey Brown, of Deptford, London; Mr. J. F. S. Snell, of St. Pancras, London; and Mr. F. L. Todd, of Glasgow. It was ultimately decided that Messrs. Snell and Brown be recommended, the final selection to be made by the Council.

TUNBRIDGE WELLS.—It has been decided by the Town Council to erect the central station in a portion of the Lower Yard near Stanley-road. The specifications and plans for the machinery have been completed, and advertisements inviting tenders have been issued.

WESTON-SUPER-MARE.—Messrs. Segundo, Bate, Ball and Metzger have each offered their services to the Board on the electric lighting subject, but a resolution that "Mr. Medhurst's offer to report fully and to advise the Electric Lighting Committee on the question of electric lighting and tramways, and on the utilisation of dust destructors for the production of electric power at a fee of 50 guineas and personal out-of-pocket expenses" be accepted, was carried, on the understanding that the Town Commissioners do not commit themselves to anything beyond the first stage of the proceedings.

WOLVERHAMPTON.—The plans for the new works to be erected in Wednesfield-road for Thomas Parker (Limited) have been approved by the Public Works Committee of the Town Council. The architect for the works, which will cover nearly five acres of ground, is Mr. A. P. Brevitt.

WORCESTER.—The Corporation have decided to lower the price per unit for the electric current from 6d. to 5d.

WORTHING.—The £200 limit agreed upon by vote of the Town Council for the cost of the experiments of the Hermite system of electrical sanitation was not reached, the expense incurred only being £169.

WREXHAM.—Mr. A. C. Baugh, architect and surveyor, has received instructions from the Altrincham Electric Supply (Limited), for the plans of the new electric light station to be built for Altrincham and Bowden. Mr. Baugh has also in hand a commission for part of the extensive new electric lighting works now being built for the Manchester Edison-Swan Company.

YARMOUTH.—The Electric Lighting Committee of the Town Council have recommended that an overhead travelling crane be provided. The surveyor has been instructed to confer with Mr. Preece to fix the rate of charge for electric current to consumers, and at the last meeting of the Council it was decided that immediately after the electric light works were started in Yarmouth, the Surveyor should report upon the lighting of Gorleston and Southtown by the electric light.

COMPANIES' MEETINGS AND REPORTS.

Swan United Electric Light Company (Limited).

An extraordinary general meeting of this Company was held yesterday at the Cannon-street Hotel, Mr. J. S. Forbes presiding.

The SECRETARY (Mr. H. Charles Gover) having read the notice calling the meeting,

The CHAIRMAN said that the object of the meeting was to give effect to what the Directors had from time to time ascertained to be the wish of a considerable majority, if not of the entire number of shareholders interested. At the last meeting of the Swan Company, although they had to deal chiefly with the accounts, he entered very fully into the matter which he now desired to lay before the shareholders. They were the proprietors of the Swan Company, and they happened in that capacity to be the largest proprietors of the Edison and Swan Company, in which they held 60 per cent. of the whole capital. Their partners, as they knew, repre-

Digitized by Google

sented Mr. Edison and his friends, and in the old days when they made an amalgamation the difficulty of carrying it out entirely was that the Edison patents were secured only for Great Britain, whereas they had secured the Swan patents for Great Britain and the rest of the world, excepting America. They had a share under the fusion of the Edison and Swan undertaking amounting to £208,000, and as holders of that security they had been for a number of years receiving in payment from that Company the dividend accruing from their investment, which they brought into a separate account, they meantime carrying on a separate business in Germany, and having also interests in France. Of course the business had developed. There were up to the present time practical difficulties in the way of dealing with this residuum, if he might so call it. It had taken some time to ascertain what was the best way to simplify matters. What they had got to sell and what the Edison and Swan Company were prepared to buy was their residuum outside that Company, of which, as he had just said, they held 60 per cent. of the business which was limited to Great Britain. They had a manufactory in Germany, they had a considerable holding in a French company for the manufacture of incandescent lamps, namely, £30,000, and they had certain patents in Germany which might or might not be of value. Meanwhile the protection period covered by the patents had gone both in this country and for the most part in Germany. They had duplicate interests, duplicate establishments, and the Directors thought that it would be very much in the interests of all the shareholders, being large holders in the Edison and Swan Company, that the residuum should be brought into the general pot. One of the conditions of the Swan Company imposed on the Edison and Swan Company was that the latter could not manufacture for exportation, and it would be greatly to their interest that restrictions of that kind should be removed. The proposal embodied in the resolution he was to propose would do so. They had the option at the end of this year, of determining whether it was worth while to go on as partners in the French Company, in which their holding was £30,000, or by agreement with their partners realise the assets and regain possession of the whole continent of Europe. At the present moment they were precluded from manufacturing lamps in England for consumption on the Continent outside Germany. There would be a greater facility of administration, unity of management, and what was, perhaps, most agreeable to the shareholders, more economy in carrying on the business which would be consolidated and conducted probably in a more efficient way, and at a greater profit than would be the case if they remained separate companies. Their capital, as they all knew, consisted of two kinds, fully-paid and partially-paid shares of £5 and £3. 10s., of each of which there were a larger number of holders. And the Board remitted to two very competent gentlemen—Mr. Swan, representing very largely the fully-paid shareholders, and Mr. Quilter, representing largely the partially-paid shareholders – to reconcile the two interests. The conclusion which those gentlemen had arrived at had been recorded, and if it were approved it would be given effect to by the agreement and resolution they were now asked to pass. After reading and explaining the heads of the agreement, he concluded by moving the resolution set out in our last issue on page 169.

Mr. QUILTER, M.P., seconded the resolution, which was carried unanimously.

A vote of thanks was passed to the Chairman and Directors, which the former briefly acknowledged, and the proceedings ended.

Sheffield Electric Light and Power Company (Limited).

The third ordinary general meeting of this Company was held on Wednesday in the Cutlers' Hall, Alderman G. Franklin presiding.

The CHAIRMAN, in moving the adoption of the report and balance-sheet, gave a brief statement of the profit and loss account for the year ending December, 1893. That year was notoriously the most unfavourable for electric lighting companies on account of the almost perpetual sunshine and the absence of fogs. Notwithstanding this, the increase had continued in the revenue derived from the sale of current. In 1892 the accounts of the Company were made up for only nine months, but equalising the periods for the purpose of comparison, it would be found that the income from the sale of current during 1893 had been £3,555. 11s., an increase at the rate of £750 a year over 1892. On the other hand, the cost of generation of electricity had increased by £180 a year, which was more than accounted for by the extra cost of fuel during the coal strike. Shareholders should also take into consideration the exceptional difficulties which the Directors had had to contend with by reason of the erection of a new electric lighting station over the site of the old, at the same time keeping the machinery going, so that the light should never be allowed to go out. The capital expenditure last year, owing to the circumstances which he mentioned, amounted to £19,689. 4s. 1d., almost entirely accounted for by the construction of the electric lighting station and also the underground mains, which were laid throughout the whole of the centre of the town. The Company were now liable to be called upon to supply 13,200 8-c.p. lamps, and had machinery enabling them to supply 15,000. The application of the Company for new shares and debentures had been subscribed particularly well, and the Directors would now be able to go forward, and give the enterprise a fair chance of becoming a good business, and securing for the Company the position of being a prominent dividend-paying concern. The balance of profit for the past year was equal to a dividend of 2½ per cent. on the capital then in the concern; but the Directors, having regard to the fact that a number of new shareholders had taken shares, thought it inadvisable to declare any dividend for last year, but to carry the balance forward to strengthen the current year's revenue. The report and balance-sheet were adopted, and the retiring Directors, Ald. Franklin and Ald. Gamble, were re-elected.

Electro-Chemical Company (Limited).

The first ordinary general meeting of this Company was held on Tuesday at the Cannon-street Hotel, under the presidency of Col. Holland, C.B.

The SECRETARY (Mr. W. J. Finch) having read the notice calling the meeting,

The CHAIRMAN stated that as the allotment of shares was made only three months ago, and as they had had a good deal to attend to since in arranging and organising the details connected with and incidental to the affairs of a new undertaking such as theirs, they had not yet been able to conclude the purchase of land for their works. Until they were in possession of the land it was impossible for them to complete contracts for buildings, plant, and machinery. They would under ordinary circumstances have delayed holding the meeting until these matters had been settled, but as the present was their statutory meeting, they were compelled by the Act of Parliament to hold it on or before the 14th inst. He was, however, glad to in form them that the more they had looked into everything relating to their affairs the more satisfied had they become that in the Electro-Chemical Company they had a genuine, sound, good business, which should prove, if properly inaugurated and efficiently worked, very remunerative to all who were interested in it. New manufacturing undertakings in these days generally had various drawbacks, to which he alluded, but this Company would be free from such disadvantages, and they would not have to sell their products at reduced prices, as prices in the alkali trade were fixed at a good and profitable figure by the Alkali Union—a great combination of almost all the alkali works in the kingdom, manufacturing chemicals which this Company proposed to make. They had allotted 16,745 Preference shares, representing £83,725, and 14,000 Ordinary shares, representing £70,000. The purchase of their patent rights had been completed, and all the British, foreign, and Colonial patent rights had been, or were in course of being transferred to the Company. No cash has yet been paid to the vendor Company, which had taken £25,000 out of the £30,000 cash due to it in shares; and the remaining £5,000 which was due had, by mutual consent, been allowed to stand over without interest for six months, and it would be paid in shares or cash according to the requirements of the Company. It was intended, in the first instance, to put up and work machinery for manufacturing about 5,000 tons of caustic soda and bleach, and after testing it, to double and quadruple the plant later on. Negotiations were now proceeding for the purchase of one of the sites that had been offered to them for their works. They hoped the plant and machinery which they now contemplated erecting might be in operation within the next few months. Negotiations were in progress for selling some of the foreign patents. The specifications of all their patents were either originally drawn up or amended and approved by Mr. Fletcher Moulton, Q.C., M.P., and they believed that they had absolutely valid patents. After speaking in hopeful terms of the profits which might be anticipated from their manufactures, and stating that Mr. James Swinburne had been appointed their consulting electrician, and that the services of Mr. J. Leith had been secured as manager of their works, he said that if anyone present doubted the practicability of making the best caustic soda and bleach by electricity, he would ask his attention to the excellent samples of soap that were on the table, which had been made by electrolytic caustic soda by the Company's process at the works of Messrs. J. C. and J. Field, of Lambeth. Mr. Field, who was a practical chemist himself, was present, and, no doubt, could tell them that electrolytic caustic soda was, from his own experience, whiter, purer, and better for making soap than any other soda made by other processes. He (the speaker), as a practical paper-maker, working one of the largest mills, and being probably one of the largest users of bleach in the kingdom, could tell them that he had made tons of caustic soda and bleach by the Company's electrolytic process, and that he had used them in boiling fibre and bleaching paper, and had found the articles in every way equal to the best he had ever bought from the Alkali Union, and perhaps a little purer and better.

On the motion of Mr. MARCUS, seconded by Mr. VOGAN, a resolution was passed confirming the appointment by the Board of Col. Holland as a Director and Chairman; and on the motion of Capt. Wemyss, Messrs. Gane, Jackson and Jefferies were elected auditors to the Company for one year.

Mr. JAMES C. RICHARDSON, the inventer of the process, afterwards addressed the meeting, and spoke highly of the prospects of the undertaking.

A vote of thanks to the Chairman closed the meeting.

Electric and General Investment Company (Limited).

The following is the report of the Directors for the year ended May 31st last, to be submitted to the fifth ordinary general meeting of shareholders to be held at Winchester House, London, E.C., on Tuesday, the 26th inst. at 3 p.m :—

The profit and loss account shows a gross profit on the transactions of the year (including the balance of £65. 16s. 5d. brought forward from last year) of £10,735. 6s. 8d., and after deducting all standing charges and the interim dividend already paid on the Ordinary shares, there remains a net balance available for distribution of £7,369. 10s. 4d. The Directors now recommend the payment of a further dividend upon the capital paid up on the Ordinary shares at the rate of 40 per cent. per annum for the past six months, and a dividend on the Founders' shares of £30 per share for the year. This will leave a balance of £369. 10s. 4d., which the Directors recommend should be added in equal moieties to the Ordinary and Founders' reserve funds. It is proposed to make the dividends payable on June 27, 1894.

The Directors who retire this year are Mr. G. Herring and Mr. B. H. Van Tromp, who offer themselves for re-election, as do the auditors, Messrs. Rait and Kearton.

NEW COMPANIES, STATUTORY RETURNS, &c.

DAWSON GAS ENGINES SYNDICATE (LIMITED).—This Company was registered on June 12, 1894, with a capital of £70,000, in £10 shares, to acquire certain inventions in the nature of engines to be worked by gas, petroleum, oil or other methods, and all the patent rights and privileges which now are or may be secured to Henry Thomas Dawson, engineer, and to carry on the business of mechanical, electrical, gas, and general engineers, electricians, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of and dealers in electrical apparatus and appliances.

ENGLISH AND COLONIAL ELECTRIC LIGHT COMPANY (LIMITED).—This Company was registered on June 11th with a capital of £50,000, in £1 shares, to acquire, work, and use patents and patent rights in connection with electricity, and in particular those of Samuel William Maquay, specified and enumerated in an agreement dated June 4th, between Samuel W. Maquay and John S. Forbes, and to carry on the business of electrical engineers, and makers or providers of electric machinery and apparatus of all kinds, or all business and matters connected with electricity, including the supply of power. The subscribers (with one share each) are:—Lewis Chalmers, M.E., William Gunn, Charles T. Kingsford, William A. Byron, William Chalmers, Charles Purrott, and Frederick W. Cartwright.

LOANDO GAS COMPANY (LIMITED).—This Company was registered on June 12th, with a capital of £50,000, in 4,000 Preference and 1,000 Ordinary shares of £10 each, to acquire the concession granted by the Municipal Board of the City of Loanda, South-West Africa, to Antonio A. Lorenço de Carvalho and Dr. Alfredo Troni, for public and private lighting in the City of Loanda, by means of gas, electricity, or other system for a period of 50 years, and to manufacture and supply gas, electricity, electric power, plant, and apparatus for all purposes.

AFRICAN TRANSCONTINENTAL TELEGRAPH COMPANY (LIMITED).—The first annual return of this Company, made up to May 24th, has been filed. 75,436 shares have been taken up out of a nominal capital of £140,000, in £1 shares. Upon 1,296 shares the full amount has been called, in upon the remaining 74,140 shares a call of 5s. per share has been made, resulting in the payment of £19,581, and leaving £250 in arrears. The principal shareholders are the Hon. Cecil J. Rhodes, of Cape Town, South Africa (28,500); Alfred Beit, of 29 and 30, Holborn Viaduct, London, E.C. (10,000); Right Hon. Baron Nathan M. Rothschild, of New Court, St. Swithin's-lane, London, E.C. (5,000); and Sigmund Neumann, of Warnford-court, London, E.C (5,000).

ALBERT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to May 18, 1893, has only been recently filed. Out of a nominal capital of £10,000, in £5 shares, 407 shares were taken up. Upon 400 of these the full amounts had been called, and upon the seven signatories' shares a call of £1 per share had been made, resulting in the payment of £2,007.

AUTOMATIC ELECTRIC RAILWAY SIGNAL COMPANY (LIMITED).—The annual return of this Company, made up to May 7th, has been filed. 4,905 shares have been taken up, out of a capital of £10,000, in shares of £1 each, and of these 3,300 have been issued as fully paid. Upon the remaining 1,605 shares, calls amounting to 15s. per share have been made, resulting in the payment of £1,010, and leaving £193. 15s. as yet unpaid.

BAILEY, GRUNDY, AND BARRETT (LIMITED).—The first annual return of this Company, made up to June 4th, has been filed, 662 shares have been taken up out of a nominal capital of £10,000, in £5 shares. Upon each of these the full amount has been called, resulting in the payment of £3,300, and leaving £10 in arrears.

EASTBOURNE ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to April 2nd, was recently filed. Out of a nominal capital of £50,000, in £10 shares, 1,017 Ordinary and 40 Preference shares have been taken up, the full amount called, and £10,570 paid. A notice was filed on June 9th, stating that a resolution for the extension of the debenture issue from £25,000 to £35,000, with the consent of the present holders, the new debentures ranking *pari passu* with present issue, was passed on March 19th, and confirmed on April 9th.

ELECTRIC WIRINGS AND FITTINGS COMPANY (LIMITED).—The annual return of this Company, made up to March 14, 1893, was only recently filed, together with the return for 1894, made up to the same date. 1,382 shares out of a capital of £5,000 in £1 shares have been taken up, and the full amount called. The calls paid have realised £1,375, leaving £7 in arrears.

ELECTRICITY SUPPLY COMPANY FOR SPAIN (LIMITED).—The annual return of this Company, made up to July 10, 1893, was only recently filed. The whole nominal capital of £100,000, divided into 19,900 Ordinary and 100 Founders' shares of £5 each, was taken up. The Founders' shares were issued as fully paid, while the full amount has been called and paid on the Ordinary shares.

EVERED AND CO. (LIMITED).—The annual return of this Company, made up to April 14, was recently filed. Out of a nominal capital of £200,000, in £10 shares, 16,496 shares have been taken up and allotted. The full amount has been called on 6,744 shares, and a call of £7 per share has been made on 9,752 shares, resulting in the payment of £135,704.

CHINA AND JAPAN TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to May 16th, has been filed. Out of a nominal capital of £20,000, in £1 shares, 14,761 have been taken up, and all have been issued as fully paid. 14,101 of these are held by the Oriental Telephone and Electric Company (Limited).

FOWLER, LANCASTER AND CO. (LIMITED).—The statutory return of this Company, made up to May 2nd, was recently filed. Out of a nomina capital of £50,000, in shares of £10 each, 554 have been taken up. Upon 54 of these the full amount has been called, and upon the remaining 500 shares calls amounting to £5 per share have been made, resulting in the payment of £3,040.

KENNEDY STORAGE BATTERY COMPANY (LIMITED).—The annua return of this Company made up to January 12, 1894, was recently filed. The whole nominal capital of £100,000 in shares of £1 each was issued as fully paid to Patrick Kennedy, of 105, Johnson-street, Brooklyn, U.S.A., and Charles J. Diss, of 334, Pearl-street, Brooklyn, N.Y., in consideration for the sale to the Company of British Patents No. 16,934 of 1891, No. 16,938 of 1891, and No. 9,014 of 1892 for "improvements in the manufacture of secondary or storage batteries." The vendors hold 23,750 shares between them, while George C. A. Kohler, of Broad-street House, London, E.C., holds 37,050.

LONDON ELECTRIC SUPPLY CORPORATION (LIMITED).—The annual return of this Company made up to May 23rd has been filed. The nominal capital is £1,250,000 divided into 200,000 Ordinary and 50,000 Preference shares of £5 each. 111,000 Ordinary and 48,050 Preference shares have been taken up and the full amount per share called. The calls paid amount to £798,990. A sum of £3,740 has been received in respect of 1,950 forfeited shares.

CITY NOTES.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended June 10th were £911, as against £759 in the corresponding period of 1893, being an increase of £152. The total receipts for the half-year amount to £20,923, as against £20,252 for the corresponding period of 1893, an increase of £671.

COMMERCIAL CABLE COMPANY.—This Company announce a quarterly dividend at the rate of 7 per cent. per annum, payable on the 2nd prox.

DERMATINE COMPANY (LIMITED).—A private meeting of the shareholders of this Company was held on Tuesday last at Winchester House, E.C.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—This Company notify that the coupon on their Five per Cent. Australian Government Subsidy Debentures, due on the 1st July next, will be paid on that date at Messrs. Barclay Bevan and Co's bank, 54, Lombard-street, E.C, Coupons must be left three clear days for examination.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—Notice is given that an extraordinary general meeting of the shareholders of this Company, will be held at Winchester House, E.C., on Tuesday, the 19th inst., at 11:30 a.m., when the resolutions passed at the meeting held on the 4th inst., for the voluntary winding-up of the Company, and the appointment of Mr. C. F. Kemp as liquidator, will be submitted for confirmation as special resolutions.

NATIONAL TELEPHONE COMPANY (LIMITED).—The transfer books of the Four and a-Half per Cent. Debenture Stock of this Company are announced to be closed from the 18th to the 30th inst. inclusive preparatory to the payment of the half-yearly interest due July 1st.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY (LIMITED).—An extraordinary general meeting of this Company was held on Tuesday, at Cannon-street Hotel, London, E.C., for the purpose of electing Directors and auditors. Mr. W. S. Schuster, who was voted to the chair, said that the proceedings were formal. The petition presented for the winding up of the Company, with a view to its reconstruction under the Court, was adjourned by Mr. Justice Vaughan Williams to give the shareholders an opportunity of expressing their views upon it. Since then the present Directors had signified their intention to retire, in order that a new Board might be constituted; and, under those circumstances, the petition would not be proceeded with. If satisfactory arrangements could not be brought about, the new Board would recommend the shareholders to litigate or wind up. Investigations made for the purpose of litigation had thrown a great deal of light upon the history of the Company, which it was not proposed, having regard to possible future litigation, to introduce to the meeting. Mr. Elliott said it was within the knowledge of the members that a petition was presented for winding up, alleging various acts on the part of the Directors and others, as grounds for so doing; but the judge, after reading the affidavits, said his opinion was that the matters stated in them were not grounds upon which he could order the winding up.—Mr. Munns said they hoped that some settlement would be come to with the debenture holders, which would take the line out of their hands, and also with the Electric Construction Corporation, by meads of which the charges which the Company was liable to pay under the contract would be modified. Ultimately, Messrs. W. S. Schuster, S. R. Blundstone and A. Dawson were appointed Directors, and the resignation of the old Board was accepted.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have ordered the vendors' shares, Nos. 7 to 214 and 719 to 10,000, of the Charing Cross and Strand Electricity Supply Corporation (Limited) to be quoted in the Official List.——Application has been made to the Committee to allow the £30,000 Four and a-Half per Cent. Debentures of the Direct Spanish Telegraph Company (Limited) to be quoted in the Official List.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended June 8th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,576.

WESTERN UNION TELEGRAPH COMPANY.—This Company has declared a quarterly dividend of 1¼ per cent.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 840.—Vol. XXXIII. FRIDAY, JUNE 22, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The interest of electrical engineers in the use of gas power for car propulsion was temporarily excited a short time ago by the favourable remarks of the President of the Institution of Mechanical Engineers in his presidential address. Our readers may therefore care to hear of an experiment in gas power propulsion which was commenced on the Croydon tramways last Tuesday. According to *The Times*, the motor is placed under the tramcar together with three cylindrical gas-holders. These three reservoirs hold a sufficient supply of gas to serve for an eight-mile run. The car is about 18ft. long, and, with the machinery, weighs 5½ tons. The motor, which is of the Otto type, and is specially constructed for tramway work, has a slow and a quick speed. The ignition of the charge in the motor cylinders is effected by electricity, and the cylinders exhaust into a condenser. At the charging station an 8-H.P. Otto engine drives a compressor. By this latter the gas, which is taken from the mains, is pumped into a steel receiver at a pressure of 150lb. per square inch. This plant is equal to the supply of five tramcars, the number which it is intended to place on the line at first. The pressure in the tramcar cylinders is about 120lb. per square inch at starting, and the cost of the gas used is stated to be 1d. per mile with a fully-loaded car.

Although apparently so direct a method of obtaining locomotion, gas power used in this way is really a very much more roundabout process than electric traction, and it involves a greater number of stages in the plant. The amount of capital per horse-power must therefore be relatively greater. Firstly, there is the series of plants belonging to the gas company, a share in the expenses of which has, of course, to be met by the tramway company. Next, there is the compressor plant, which must be adequate to compress gas at the maximum rate. Then there is the reservoir or storage plant. Lastly comes the gas motor with its system of gearing. From the point of view of capital charges, therefore, we are inclined to think that this system has some serious difficulties to surmount—the difficulties in working expenses, and the mechanical difficulties will probably be no less formidable. That great traction bugbear, the starting effort, must tell more forcibly upon gas motor plant—upon its reliability and on the margin of power which must be held in reserve—than on electromotors. Again, the necessity for cooling the cylinders must involve a very grave difficulty. However, the car is actually running, and it will be interesting to see with what measure of success its running may be continued.

In our issue of June 1st we commented on the apparently unfavourable verdict given by trials of the Welsbach light in the streets of Munich. Since then, however, Herr Murchall, of the Wiesbaden Gas Works, has quite another tale to tell. According to his experience with from 37 to 471 burners, the delicate constitution of the incandescent gas-burners withstands the "thousand natural shocks" of an open-air life far better than would have been thought possible; and Herr Murchall's figures as to cost, candle-power, duration, and gas consumption are worth attention. A light of some 60 candles can be obtained for a consumption of 3½ cubic feet of half-crown gas per hour. Chimneys, costing 6d., have to be renewed about every 600, and mantles, costing 1s. 6d., about every 500 hours. The falling off in candle-power during this brief span of life is barely 4 per cent., though a mantle, the existence of which is protracted to the Methuselah age of 2,000 hours, gives 46 candles instead of the 60 candles of its prime. The Welsbach light has not, however, as yet become quite indifferent to its surroundings, since its life when placed on a bracket is decidedly longer than on an ordinary lamp-post. From Glasgow we learn that the electric lighting of the streets is not to be extended; but the incandescent gas lamp is to be tried. It is evident that electricians must be prepared with a counterblast to this latest device of the enemy; that is to say, if street lighting according to the present practice be worth fighting for at all, which may well be doubted, except from the advertising point of view.

A Paper by O. Lehmann which we print elsewhere records some observations on the local alteration of colour and the segregation of the pigment to which the colour is due, produced by the passage of a current of high pressure through a badly-conducting liquid. Halos form at each electrode, and their advance is retarded, and the ease of their observation is enhanced by increasing the viscosity of the liquid in which they are formed by the addition of glycerine or sugar thereto. From the detailed account of the experiments referred to above, it appears that the electrolytic decomposition of the colouring matter is attended by the diffusion of the products and their encounter at a point intermediate between the electrodes, where actual mechanical disturbance, resulting in the deposition of the re-formed pig-

Digitized by Google

ment, occurs. Thus, Congo red (amidosulphonaphthaleneazodiphenylazonaphthylamine sulphonic acid), which is a fairly sensitive indicator, becoming blue with acids and red with alkalies—the reverse of the colour change of ordinary litmus—gives not only, as might be expected, a blue colour at the anode and a red at the cathode, but yields a precipitate of pigment at the point where the two halos of colour meet. Liquids enmeshed in gelatine, their free movement being thus hindered, proved particularly suitable for the study of the action of currents at pressures that would have tended in ordinary mobile solution to an unduly rapid translation of the decomposition products.

In the Foreign Abstracts of the *Proceedings* of the Institution of Civil Engineers, Vol. CXVI., there is an interesting account of an investigation which has recently been made by M. P. Joubin, into the law of magnetisation of soft iron. This investigation forms the subject of a Paper communicated to the Académie des Sciences. Struck by the similarity existing between the curves, which represent the relation existing between the intensity of magnetisation and the susceptibility of the object submitted to that intensity, and the curves which represent the density of a saturated solution as a function of the temperature, the author has transformed Van der Waal's well-known formula for the density and pressure of a gas into corresponding quantities in magnetic terminology, and arrives then at Frölich's formula for the magnetic circuit, which was enunciated by empirical solution of numerous experimental researches. As in the fluid instance, there is an abrupt change in the curve when the vapour tension becomes zero, and a change of state occurs, so there is an abrupt change in the magnetic curve, and it is the intention of the author to investigate this point, and to obtain if possible a simple fundamental equation for the magnetic resistance.

Cable Extension.—The Halifax Board of Trade has unanimously passed a resolution asking the Dominion Government to subsidise an extension of the Bermuda cable to Jamaica.

Waterloo and City Railway.—Work on the electric railway between the City and Waterloo Station has been commenced by the contractors, Messrs. John Mowlem and Co.

Royal Society.—The following Papers were down for reading yesterday:—Sir D. Salomons, Bart, "On Some Phenomena in Vacuum Tubes;" Alexander P. Trotter, "The Rotation of the Electric Arc."

Cambridge.—Notice has been issued by the Cambridge Electric Supply Company that, on and after October 8th, there will be an uninterrupted supply of current at all hours of the day and night throughout the year.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Brest-St. Pierre (P.Q. Co.) ...	Mar. 29, 1894	June 13, 1894.
Bissao-Bolama	Nov. 24, 1893	—
Tarifa-Tangier	June 12, 1894	—

Electrical Bills in Parliament.—On Friday last week the London County Council (General Powers) Bill was read a second time in the House of Lords. The Central London Railway (Extension of Time) Bill was read a third time and passed.

Cable Laying.—The "Faraday" has picked up the Irish shore end of the Commercial Cable Company's new cable between Ireland and Nova Scotia, which was laid in April, and having spliced on the deep sea section is now paying out westward.

Telegraphic Communication in Western Australia.—Although the foreign business increased to the extent of £13,000, the returns of the Telegraph Department of Western Australia show a falling-off in receipts during last year of £7,586.

A Turkish Treatise on Telegraphy.—We are given to understand that the Turkish Council of State at Constantinople has decided to publish at the expense of the State a treatise on telegraphy giving all the information required by telegraphists and the public in general.

Indian Telegraphs.—The Revenue earned by the Indian Telegraph Department during 1893-94 shows an increase of four lakhs of rupees on private messages, as compared with the previous year. There has been a decrease of one lakh in expenditure on State telegrams.

Society of Arts.—The Council of the Society of Arts have awarded one of their silver medals to Mr. W. Worby Beaumont for his Paper on "Automatic Balance of Reciprocating Machinery, and the Prevention of Vibration." The thanks of the Society were voted to Mr. W. H. Preece for his Paper on "Electric Signalling Without Wires."

King Conduit System of Electric Traction.—The King system of electric traction with underground conduit is being tried on the Tenleytown Railway at Washington, D.C. Two ploughs on the car force back the flexible cover of the slot, which consists of hinged iron plates with a continuous strip of water-proof rubber belting underneath. The cost is estimated at £2,000 to £2,400 per mile.

The Consumption of Gas in Paris.—The quantity of gas supplied to Paris and the 59 suburban parishes was, during the year 1893, nearly 11 million thousand cubic feet, or less than the quantity supplied in 1892. The output of 1892 was itself less than that of 1891. The diminution is 1·75 per cent., which is a good deal less than the diminution reported by the Gas Light and Coke Company.

The British Association Report for 1893.—The transactions of the British Association for 1893, being the report of the meeting at Nottingham, have been published. Only two of the Papers read have been ordered to be printed *in extenso*. One is the Paper by Mr. W. Worby Beaumont on "The Automatic Balance of Reciprocating Mechanism," and the other is by Prof. Frankland on bacteriology.

Northern Society of Electrical Engineers.—A visit is to be paid by this Society to-morrow to the Liverpool Overhead Railway generating station, and the Oldham Place central station of the Liverpool Electric Supply Company. Arrangements are also being made for an excursion to the Antwerp Exhibition in July. Upwards of 20 members have already signified their intention of joining the party.

Nelson.—An additional engine and dynamo have been satisfactorily started in the electric-generating station of the Nelson Corporation. The Corporation has now been supplying electric energy for 18 months without a single failure. This installation has made a profit the first year with the selling price at 5d. per unit. The generating station is situated at the gasworks, and is superintended by a son of the gas manager.

Electrical Utilisation of Water Power.—An important electric power generation and transmission plant is now being erected on Williamette River, at a distance of about 12 miles from the town of Portland, Oregon. At this point the river falls 40ft., and there is available some 16,000 H.P. Some 20 Victor turbines, having an aggregate capacity of 12,000 H.P., are to be erected, and will drive alternators by means of belting. The current will be transmitted to Portland, and utilised there.

The City Transformer Sub-Stations.—There are in all twenty-two transformer stations in the City of London, whose situations are as follows, viz.:—Bartholomew Close, Crosby-square, Coleman-street, Falcon-square, Farringdon-street, Finsbury-circus, Fetter-lane, Lime-street-square, Milk-street, New-square, (Minories), Red Cross-street, Rood-lane, Salisbury-square, St. Andrew's-hill, St. James's-place (Duke-street), Watling-street, and Warwick-square; Copthall-avenue, St. Benetfink-churchyard (at the rear of the Royal Exchange), Queen

Digitized by Google

Victoria-street (St. Nicholas-churchyard), Nicholas-lane (in churchyard), and Pancras-lane.

Electro-Chemistry in Germany.—Electro-chemistry is making great progress in Germany at the present time. The electro-chemists have already a society of their own, and also a technical organ, and now we learn that it is desired to see established in connection with the well-known German Technische Hochschüle, Chairs of Electro-Chemistry. A deputation consisting of representatives of the Union of Industrial Chemists of Germany and the German Electro-Chemical Society recently waited on the Ministers of Finance and Education in Berlin with the object of asking that provisions for such Chairs be made in next year's estimates. The deputation was well received, the ministers promising to give the matter their consideration. According to later information, Chairs of electro-chemistry are to be founded at the Polytechnic Academies of Berlin, Hanover, and Aix-la-Chapelle.

Electrical Utilisation of Water Power in Austria and Hungary.—Messrs. Brown, Boveri and Co., of Baden, Switzerland, have recently put down an electric-power transmission plant at Burrida. The machinery, which is driven by water power, the hydraulic plant having been supplied by Signor Albertos Riva of Milan, comprises three generating machines of 150H.P., and three motors of the same power. The energy generated is transmitted to the cotton-spinning mills of Messrs. Amman and Co., one at Pordenone, and one at Fiume, at distances of 2½ miles and 6½ miles respectively. It is stated that a syndicate has acquired the Austrian and Hungarian patent rights of carborundum, and is establishing works for its manufacture at Benatek. The machinery at the works is to be driven by electricity, it being intended to put down a plant for the electrical utilisation of certain available water power.

Technical Education.—*Nature* announces that the Scottish Association for the Promotion of Technical and Secondary Education have presented a memorial to Mr. Acland asking that the yearly examinations of the Department of Science and Art shall be held in the day as well as in the evening. It is pointed out that originally arranged, as they were, to suit the convenience of artisan pupils who could not be expected to attend during the day, these evening examinations are now taken by large and increasing numbers of pupils of secondary and higher grade schools. While, therefore, fully recognising the necessity which exists for examinations in all stages of art and science subjects being continued in the evenings as heretofore, the memorialists urge the desirability of provision being made by the Department for the examination, within school hours, of pupils attending day schools.

Lamp Shades.—Referring to M. Dupré's letter to *The Times* of May 23rd (*The Electrician*, May 25th, p. 96), Messrs. J. R. Crompton and Bros., of Elton Paper Mills (Lancs.), stated in *The Times* of Tuesday that since reading the letter they have made numerous experiments, and particularly with the chrome colours, and in no single instance can they get any one of them to fire spontaneously. They have had the papers in question heated in a heating-chamber to nearly 400°F., with the result that in every case the papers when taken therefrom remained in their original uninjured condition, notwithstanding their being subjected to the heat named for several hours. They have also saturated the papers with chromic acid and dried them, and even after this severe test have failed to get them to fire spontaneously at the heat named, or under similar circumstances.

Barmen.—According to *Engineering*, an electric rack tram line has been erected at Barmen, to the designs of Messrs. Siemens and Halske. The rack line is about 1 mile long, the total rise being 550ft. The average grade is thus about 1 in 10; but the steepest portion is 1 in 5·4. The sharpest curve on the line has a radius of 500ft. The rack is of the Riggenback pattern, having teeth 3½in. long set at a 3in. pitch. It has been constructed in sections 10ft. long. Both rack and adhesion rails are fixed to the same sleepers, which are of steel spaced at 40in. centres. To prevent a bodily slipping down of the whole line, concrete anchors are sunk in the ground below the rails at intervals of 50 to 60 yards, to which a couple of the sleepers are firmly secured. The cars used have accommodation for 28 passengers, and are fitted with two 36-H.P. electric motors. Overhead conductors are used for conveying the current to the cars. Steam is used to supply power at the generating station.

A Bird in the Hand is worth Two in the Pipe.—For about an hour and a-half on the morning of the 7th inst. the electric lighting in the streets of Bath failed. Mr. Gatehouse reports that the failure "was due to a sparrow's nest having been built in the pipe which conveys the leads up the side of No. 10, Stall-street, to lamp No. 6. The nest probably pressed the leads close to the side of the pipe, and the rain trickling down the pipe saturated the nest with moisture, forming a semi-connecting circuit between them. These leads (or conductors) are covered externally with prepared hemp and jute, which absorb moisture readily, and when they become saturated act in conjunction with the insulating material beneath them as a kind of condenser. When in this condition they are sufficiently close together for a small induced spark to pass, which ultimately destroys the insulation. This appears to have occurred in the present case, with the result that the nest took fire and the insulation broke down at this point."

Electric Lighting in Japan.—A state of affairs regarding electric lighting in Japan, which is not without its moral, has come to light in connection with the recent celebrations of the silver wedding of the Mikado of Japan, when the Imperial palace was lighted by no less than 1,000 candles. Originally the rooms were lighted by electricity, and the magnificent electroliers constituted quite a feature of their internal decoration. It appears, however, from a Japanese paper that the installation, although superintended by a foreign expert, was more or less defective from the first, and complete confidence in immunity from fire was never felt. After the destruction of the Parliament buildings some years ago by fire, which catastrophe was generally attributed to the electric lighting, the Mikado conceived a dislike and distrust of that method of illumination, and that fact supplementing the uneasiness already felt about the security of the installation in the palace, settled the doom of the whole affair, candles having ever since been used.

Lawrence Conduit System of Electric Traction.—The Lawrence Electric Company, of New York, are bringing forward a new form of conduit for electrical lines. The essential feature of the system is a working conductor consisting of a section of a T-shaped rail 32ft. long, which is carried on pivoted arms placed in the conduit. Each section of rail is insulated from those before and behind it, but is joined to them by plates of hard vulcanised fibre. All sections of the conductor, save those under the trolley, are completely insulated from the main lead from the generating station, which is laid alongside the track. The current collector depresses the conductor section immediately underneath, being able to do so, since this section is supported on pivoted arms or levers, the other ends of which then make contact with the main from the generating station. The current can then pass through these arms to the conductor section, and thence through the collector to the car. The plant is said to have worked well, even when the track and conduit were flooded with 3ft. of salt water.

A 10,000-Volt Arc Light Dynamo.—Considerable interest attaches to a new type of arc light dynamo recently brought out by the Excelsior Electric Company, of America. The machine is the first 10,000-volt continuous current dynamo designed for running arc lamps in series, and it has a capacity of 200 10-ampere lamps. The general design of this machine is on the lines of the 5,000-volt Hochhausen dynamo, for 100 lights, brought out by the same Company some four years ago. It runs at a speed of 625 revolutions per minute, developing 10 amperes at 10,000 volts. There are 48 coils on the armature, each consisting of 220 turns or windings; and there are, of course, 48 commutator segments. The external diameter of the armature ring is 33in., and its internal diameter 20in. The ring is of square section, 6·5in. each way. The pole-pieces are hinged so that they can be swung back for inspection. There is only one bearing, namely, in the interior between the armature and

Digitized by Google

the pulley. The weight of the complete machine is 7 tons 2cwt. 96lb. The regulation of a machine of this type is no easy matter; it is effected, in the present case, by means of a supplementary electromotor, arranged to shift the brushes according to the load. This motor is controlled by a constant-current regulator. It is said that the flashing which results is by no means abnormal, which, however vague, is probably nearer the truth than if it had been said the flashing is small.

Boiler Explosions.—We have received a copy of the last Report of the National Boiler and General Insurance Company. The whole of this report is well worth reading, and it contains much valuable information for steam users. Among the records of boiler explosions we notice two which may be of special interest. The first of these was a Babcock and Wilcox boiler, which burst a tube and caused one death, owing to the accumulation of mud deposits in the headers and about the ends of the tubes at the back of the boiler. The rupture occurred along about 4ft. 8in. of the tube, and commenced at about 2ft. 6in. from the front end. The engineer who had charge of the boiler was found to have been very negligent, and the direct cause of the explosion was over-heating of the tube due to infrequent cleaning. The second explosion we may notice relates to an economiser, consisting of 224 pipes. It appears that this large economiser was fitted with only one safety-valve, and the explosion occurred during a time when this valve had been removed for repair. There was no pressure-gauge on the economiser. Owing to the bad fit of the economiser dampers, which were closed, a considerable quantity of hot gas escaped into the economiser flue and raised steam sufficiently to burst a pipe. The Company recommends that two safety-valves be fitted to all economisers, and more than this where the number of pipes is very large.

Overhead Troubles from Railway "Earth" Currents.—In building the extension of the Fifth-avenue branch of the Brooklyn Elevated Railroad to the city line at Sixty-seventh-street and Third-avenue the Company found difficulty in securing certain property rights between Thirty-eighth-street and Fifth-avenue and Fortieth-street and Third-avenue. Pending the settlement of this matter the structure south from Fortieth-street was erected. Upon its completion the work of joining the two parts was pushed forward, commencing at Thirty-eighth-street, the former terminus. Whilst hoisting into position the first of the last four 65ft. longitudinal girders necessary to connect the two sections, the end not yet in position came in contact with the transverse girder. Immediately the metal was melted and an electric arc was formed, and the melted iron fell to the street. After several attempts to swing the girder into position, the engineer succeeded in locating the trouble. The insulation of one of the positive feed wires of the Brooklyn City Railroad's trolley line, which were strung on one side of the elevated posts, had so worn that the live wire came in contact with the structure. The negative cable, which completed the circuit, reached the ironwork from underground at a point on the other side of the unfinished section, and the contact between the two parts of the structure completed the circuit and caused the fusion.

An After-Dinner Phenomenon.—When the guests adjourned to the engine room of the Portsmouth electric supply station after the inaugural banquet, they found one of the alternators at work, and the place brilliantly illuminated by the arc lamps. The other alternator was then started, and the massive fly-wheel, crowned with a diadem of glittering copper coils, began to smoothly turn, gradually quicken, and finally spin round at full speed. But as it did this, the bystanders were amazed to see the rim slowly revolving the wrong way, while the crank and piston rod were running on without change. In another moment the field magnets stopped, and then began to turn the right way, but leisurely. Again they reversed, and finally stopped! Some of the guests gave vent to expressions of amazement; but the more cautious, remembering the good things generously provided by the mayor, rubbed their eyes, clutched a hand-rail and held their tongues. The precursory symptoms of a plague which devastated Jeddah some time ago were strange hallucinations. An English resident stained his dog blue, and painted it with red stripes and yellow spots. It ran about the streets for a week, and nobody made a single remark about it. It is only necessary to add that the rectified current, giving as it does one hundred flickers per second, shows a series of momentary glimpses of the armature, which, if running synchronously, appears stationary, and if a little slow or fast, seems to revolve backwards or forwards.

Systematic Workshop Instruction.—Some time ago, says Mr. Franklin L. Pope in the *Engineering Magazine*, the General Electric Company established at its works in Schenectady a student's course of instruction in electrical engineering, intended for young men who have had at least three years' experience in electrical or machine-shop work, or who have obtained from some technical institution the decree of civil, mechanical, or electrical engineer. At first the Company felt compelled to exact a fee for admission to this course, but experience soon demonstrated that this had the effect of excluding the very kind of men who were likely to be of most value to the Company—those who had worked their own way through college, but who could not afford to pay the fee, and hence the requirement was abolished. The object of the course is to give the student a thorough practical knowledge of the various processes through which a piece of electrical apparatus is carried while in course of construction, and also of the electrical and mechanical principles involved in the different operations. He is placed for a stated time in each of the departments of the works, in which he is required to perform actual work under the supervision of the foreman, and receives such instruction as will enable him to do so. The time occupied by the complete course is ordinarily expected to be about two years, and the learner is paid at rates varying from 8 to 17½ cents per hour, according to his experience and proficiency. The students are required in all cases to observe the same rules and regulations as the regular workmen respecting conduct and hours of work. It is stated that the complement of students is at present filled, and that there is likely to be no vacancy during the present year.

The Oxford Meeting of the British Association.—There are already signs, says *Nature*, that the meeting of the British Association, to be held this year at Oxford, will be a success. It is unfortunate, perhaps, that the City of Oxford is this year destitute of municipal buildings, the old buildings having been pulled down, while the new have scarcely their walls raised to the level of the first floor. But this deficiency is amply compensated by the numerous University and College buildings which have been placed at the disposal of the Local Executive Committee. The reception room will be in the entrance hall of the new Examination Schools in High-street. Section A (Mathematical and Physical Science) will meet in the Lecture Theatre of the Clarendon Laboratory, and the allied Section G (Mechanical Science) will meet in close contiguity in Keble College Hall. Section B (Chemistry) will meet in the Chemical Theatre, and for larger meetings will have the use of the large Lecture Theatre in the Museum. The proceedings will begin on the evening of Wednesday, August 8th, when Prof. Burdon Sanderson will resign the presidency, and the new President, the Marquis of Salisbury, Chancellor of the University, will deliver the opening address. On the Thursday evening there will be a conversazione in the University Museum. On the Friday evening Mr. W. H. White, C.B., will give an evening lecture in the Sheldonian Theatre, on "Steam Navigation at High Speeds." The Saturday evening lecture to working men will be given by Prof. Sollas; and Tuesday evening will be occupied by a conversazione. Invitations to foreign investigators have been issued by the Local Executive Committee, and nearly eighty have already signified their intention to attend the meeting. Nearly every prominent English man of science has already expressed his intention of being present, and there can be little doubt that the Oxford meeting of 1894 will equal in interest the last Oxford meeting of 1860, which was made celebrated by Prof. Huxley's spirited defence of the then novel doctrine of Darwinism. The local secretaries for the Oxford meeting are Messrs. G. C. Bourne, G. Claridge Druce, and D. H. Nagel, and any communications respecting the meeting should be addressed to them at the University Museum, Oxford.

BOILER TRIALS.*

Some careful trials of the Babcock-Wilcox boilers at the Bankside station of the City of London Electric Lighting Company have recently been undertaken, with a view to determine the most economical class of fuel and the best method of stoking it. We are able to give, this week, a summary of the results of these trials.

Summary of Trials of Boilers at the City of London Electric Lighting Station, Bankside, E.C.

—	Babcock and Wilcox Boilers.	
	Hand-firing.	Vicars' Patent Mechanical Stoking System.
Date of trial	April 26, 1894.	June 4, 1894.
Duration of trial	Nine hours.	Six hours.
Description of fuel used	Nixon's Navigation.	Bituminous rough, small.
Price of fuel used per ton	16s.	10s.
Fuel consumed	13,664lb.	9,184lb.
Ashes and clinker	532lb.	1,022lb.
Weight of combustible	13,132lb.	8,162lb.
Per cent. of ash	3·9	11·1
Draught in flues (average)	0·48in.	0·55in.
Temperature in flues (average)	412°F.	453°F.
Water evaporated	118,535lb.	82,100lb.
Temperature of feed water	54·3°F.	62°F.
Average steam pressure	145·9lb.	157·5lb.
Water evaporated per hour	13,170lb.	13,683lb.
Water evaporated per pound of fuel used	8·67lb.	8·94lb.
Ditto per pound of combustible	9·02lb.	10·05lb.
Ditto per pound of fuel used, from and at 212°F.	10·50lb.	10·78lb.
Ditto per pound of combustible from and at 212°F.	10·93lb.	12·12lb.
Cost of evaporating 500 gallons of feed water, in pence	40·8	24·8

Our readers will be interested to know that, in consequence of these trials, all the boilers at the Bankside station of the City of London Electric Lighting Company are forthwith to be fitted with the Vicars mechanical stokers and coal-conveying and elevating plant. We may point out that the essential fact to be deduced from the trials is that an equivalent or slightly better evaporation per pound of coal is to be obtained from the steady continuous stoking of cheap bituminous slack by mechanical means, than can be obtained from the best and most costly qualities of smokeless steam coal fired by hand. The chief element of saving lies in the reduced cost of the coal per ton, the evaporation per pound of the bought coal being only slightly improved (in this case, at any rate) by the use of the mechanical appliances. Our readers will remember that this electric light company was under an injunction to cease from causing smoke to escape from the works chimney, during the time when, owing to the coal strike, it was compelled to burn inferior fuel by hand firing. But though inferior bituminous coals cannot be fired by hand without developing heavy smoke, it has been demonstrated over and over again that their combustion may be quite smokeless if carried on by mechanical coking firing, such as is now to be adopted at Bankside. A further point of interest in the trials lies in the fact that the well-known Babcock-Wilcox water tube boilers were tested. These boilers up to the time the trials were undertaken had invariably proved themselves better adapted to the production of steam from smokeless dry coals, and had not given very satisfactory results with bituminous coals. It is therefore interesting to observe that, with continuous coking firing, very good results with cheap bituminous slack may be obtained in this class of boiler.

* Compiled from "Motive Power and Gearing," a forthcoming work to be published by *The Electrician* Printing and Publishing Company.

ON THE FINDING OF FAULTS IN COILS WOUND ON CONDUCTING BOBBINS.

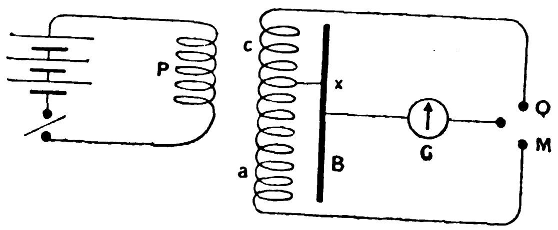
BY ALBERT CAMPBELL, B.A.

In many galvanometers and other measuring instruments, as well as for the field-magnets for dynamos and motors, it is usual to have coils of insulated wire of many turns wound on metallic bobbins. Unless the winding is done with care, sometimes faults are found in a coil, such as points where the wire is almost short-circuited to the metallic bobbin.

A short time ago a field-magnet coil was brought to the writer to be tested. Ordinary resistance tests showed that between the coil and the bobbin there was a fault of about 100 ohms resistance. As this resistance was found to be very unsteady, resistance tests were abandoned, and the writer devised the following simple method of localising the fault by induced currents. As far as he knows, it is novel, and it certainly proved quite effective; for, on unwinding the coil, a little sharp piece of brass turning was found to have pierced the vulcanised fibre insulation quite near the point predicted by the test.

The method of carrying out the test will be made more clear by reference to the accompanying diagram, in which $a\,c$ represents the coil to be tested, B being the bobbin on which it is wound.

A fairly high resistance galvanometer, G, has one of its terminals connected to the bobbin B, whilst the other terminal can be connected at will with either of the free ends of the coil at M and Q. A number of turns of insulated wire, P, are wound over the coil to be tested; this coil P we shall denominate the primary. Let the fault be at x.



G is now connected to M, and a fairly strong current is switched on in the primary P. The throw of the galvanometer is observed. G is next connected to Q instead of M, the same current is switched on again in P, and the new throw is observed in the galvanometer.

If the two throws be D_1 and D_2 respectively, we have approximately

$$\frac{\text{No. of turns in branch } a}{\text{No. of turns in branch } b} = \frac{D_1}{D_2}.$$

This relation at once localises the fault x in the coil.

A few remarks should be made on the practical working of the test. It will be noticed that if the galvanometer be fairly sensitive, a fault of high resistance presents no difficulty. If the resistance of the fault be variable, the galvanometer resistance ought to be high compared with the fault resistance. If possible, a ballistic mirror galvanometer should be used. The test may be roughly done, however, with any form of detector or galvanometer in which the swings are fairly proportional to current impulse. If the galvanometer is not sensitive enough, an iron core should be inserted in the coil. This, if practicable, should consist of strips of sheet iron, whose ends are doubled round so as to overlap and form a closed magnetic circuit. In this case we get a far greater flux of magnetic lines, and therefore much larger throws on the galvanometer. Besides, since by far the greater proportion of the lines go through the iron, we may assume with great accuracy that a given primary current will insert the same number of lines of force into the circuit a as into the circuit c. Without a closed iron circuit this is only roughly approximate, and that only where the coil is shallow in comparison with its diameter. If preferred, the primary coil need not be wound over the coil to be tested, but may instead be wound on the iron core or on a bobbin to be slipped over the core.

Digitized by Google

Of course, if an alternating-current supply is available, and a suitable voltmeter, the method may be modified by putting the voltmeter in place of the galvanometer, and using alternating current in the primary P. The voltmeter would have to be of high resistance, or an electrostatic one.

Without a galvanometer at all, a very rough test may be made by simply placing a compass needle at the centre of the coil, and observing its deflections when one pole of a battery (with high resistance in circuit) is connected to the bobbin, whilst the other pole is joined successively to the two free ends of the coil.

THE WORK OF HERTZ.*

(Concluded from page 190.)

Holtz Sparks not exciting Tube: except by help of a polished knob.

The powerful disturbance caused by the violent flashes of a Wimshurst or Voss machine it is blind to. If the knobs of the machine are well polished it will respond to some high harmonics, due to the vibrations in the terminal rods, and these are the vibrations to which it responds when excited by a coil. The coil should have knobs instead of points. Sparks from points or dirty knobs hardly excite the coherer at all. But hold a well-polished sphere or third knob between even the dirty knobs of a Voss machine, and the coherer responds at once to the surgings got up in it.

Feeble short sparks again are often more powerful exciters than are strong long ones. I suppose because they are more sudden.

This is instructively shown with an electrophorus lid. Spark it to a knuckle, and it does very little. Spark it to a knob and it works well. But now spark it to an insulated sphere, there is some effect. Discharge the sphere, and take a second spark, without recharging the lid. Do this several times, and at last, when the spark is inaudible, invisible, and otherwise imperceptible, the coherer some yards away responds more violently than ever, and the spot of light rushes from the scale.

If a coherer be attached by a side wire to the gas pipes, and an electrophorous spark be given to either the gas pipes or the water pipes or even to the hot-water system in another room of the building, the coherer responds.

In fact, when thus connected to gas-pipes one day when I tried it, the spot of light could hardly keep five seconds still. Whether there was a distant thunderstorm, or whether it was only picking up telegraphic jerks, I do not know. The jerk of turning on or off an extra Swan lamp can affect it when sensitive. I hope to try for long-wave radiation from the sun, filtering out the ordinary well-known waves by a black-board or other sufficiently opaque substance.

We can easily see the detector respond to a distant source of radiation now, viz., to a 6in. sphere placed in the library between coil knobs.

Also I exhibit a small complete detector made by my assistant, Mr. Davies, which is quite portable and easily set up. The essentials are all in a copper cylinder three inches by two. A bit of wire a few inches long, pegged into it, helps it to collect waves. It is just conceivable that at some distant date, say by dint of inserting gold wires or powder in the retina, we may be enabled to see waves which at present we are blind to.

Observe how simple the production and detection of Hertz waves are now. An electrophorus or a frictional machine serves to excite them, a voltaic cell, a rough galvanometer, and a bad contact serves to detect them. Indeed, they might have been observed at the beginning of the century, before galvanometers were known. A frog's leg or an iodide of starch paper would do almost as well.

A bad contact was at one time regarded as a simple nuisance because of the singularly uncertain and capricious character of the current transmitted by it. Hughes observed its sensitiveness to sound-waves, and it became the microphone. Now it turns out to be sensitive to electric waves if it be made of any oxidisable metal (not of carbon), and we have an instrument which might be called a micro-something, but which, as it appears to act by cohesion, I call at present a coherer. Perhaps some of the capriciousness of an anathematised bad contact was sometimes due to the fact that it was responding to stray electric radiation.

The breaking down of cohesion by mechanical tremour is an ancient process, observed on a large scale by engineers in railway axles and girders; indeed, the cutting of small girders by persistent blows of hammer and chisel reminded me the other day of the tapping back of our cohering surfaces after they have been exposed to the welding effect of the electric jerk.

If a coherer is shut up in a complete metal enclosure, waves cannot get at it, but if wires are led from it to an outside ordinary galvanometer, it remains nearly as sensitive as it was before (nearly, not quite), for the circuit picks up the waves and they run along the insulated wires into the closed box. To screen it effectively, it is necessary to enclose battery and galvanometer and every bit of wire connection; the only thing that may be left outside is the needle of the galvanometer. Accordingly, here we have a compact arrangement of battery and coil and coherer, all shut up in a copper box. The coil is fixed against the side of the box at such height that it can act conveniently on an outside suspended compass needle. The slow action of the coil has no difficulty in getting through copper, as everyone knows; only a perfect conductor could screen off that, but the Hertz waves are effectively kept out by sheet copper.

It must be said, however, that the box must be exceedingly well closed for the screening to be perfect. The very narrowest chink permits their entrance, and at one time I thought I should have to solder a lid on before they could be kept entirely out. Clamping a copper lid on to a flange in six places was not enough. But by the use of pads of tinfoil, chinks can be avoided, and the inside of the box becomes then electrically dark.

If even an inch of the circuit protrudes, it at once becomes slightly sensitive again; and if a single branch wire protrudes through the box, provided it is insulated where it passes through, the waves will utilise it as a speaking tube, and run blithely in. And this whether the wire be connected to anything inside or not, though it acts more strongly when connected.

If wires are to be taken out of the box to a coherer in some other enclosure, they must be enclosed in a metal tube, and this tube must be well connected with the metal of both enclosures, if nothing is to get in but what is wanted.

Similarly, when definite radiation is desired, it is well to put the radiator in a copper hat, open in only one direction. And in order to guard against reflected and collateral surgings running along the wires which pass outside to the coil and battery, as they are liable to do, I am accustomed to put all these things in a packing case lined with tinfoil, to the outside of which the sending hat is fixed, and to pull the key of the primary exciting circuit by a string from outside.

With reference to the reflecting power of different substances it may be interesting to give the following numbers, showing the motion of the spot of light when 8in. waves were reflected into the copper hat, the angle of incidence being about 45deg., by the following mirrors:—

Sheet of window glass..................	0	or at most 1 division.
Human body..............................	7	divisions.
Drawing board............................	12	,,
Towel soaked with tap-water...........	12	,,
Tea-paper (lead ?)........................	40	,,
Dutch metal paper	70	,,
Tinfoil	80	,,
Sheet copper................................	100	and up against stops.

Even then, with the lid of the hat well clamped on, something gets out, but it is not enough to cause serious disturbance of qualitative results. The sender must evidently be thought of as emitting a momentary blaze of light which escapes through every chink. Or, indeed, since the waves are some inches long, the difficulty of keeping them out of an enclosure may be likened to the difficulty of excluding sound; though the difficulty is not quite so great as that, since a reasonable thickness of metal is really opaque. I fancied once or twice I detected a trace of transparency in such metal sheets as ordinary tinplate, but unnoticed chinks elsewhere may have deceived me. It is a thing easy to make sure of as soon as I have more time.

One thing in this connection is noticeable, and that is how little radiation gets either in or out of a small round hole. A narrow long chink in the receiver box lets in a lot; a round hole the size of a shilling lets in hardly any, unless, indeed, a bit of insulated wire protrudes through it like a collecting ear trumpet.

It may be asked how the waves get out of the metal tube of an electric gas-lighter. But they do not; they get out through the handle, which being of ebonite is transparent. Wrap up the handle tightly in tinfoil, and a gas-lighter is powerless.

Optical Experiments.

And now in conclusion I will show some of the ordinary optical experiments with Hertz waves, using as source either one of two devices; either a 6in. sphere with sparks to ends of a diameter (Fig. 20), an arrangement which emits 9in. waves, but of so dead-beat a character that it is wise to enclose it in a copper hat to prolong them, and send them out in the desired direction; or else a 2in. hollow cylinder with spark knobs at ends of an internal diameter. This last emits 3in. waves of a very fairly persistent character, but with nothing like the intensity of one of the outside radiators.

As receiver there is no need to use anything sensitive, so I employ a glass tube full of coarse iron filings, put at the back of a copper hat with its mouth turned well askew to the source,

* A lecture delivered at the Royal Institution on Friday, June 1st, by Prof. Oliver Lodge, F.R.S., ably assisted during both preparation and performance by Mr. Edward E. Robinson.

Digitized by Google

which is put outside the door at a distance of some yards, so that only a little direct radiation can reach the tube. Sometimes the tube is put lengthways in the hat instead of crossways, which makes it less sensitive, and has also the advantage of doing away with the polarising or rather analysing power of a crossway tube.

The radiation from the sphere is still too strong, but it can be stopped down by a diaphragm plate with holes in it of varying size clamped on the sending hat.

Having thus reduced the excursion of the spot of light to a foot or so, a metal plate is held as reflector, and at once the spot travels a couple of yards. A wet cloth reflects something, but a thin glass plate, if dry, reflects next to nothing, being, as is well known, too thin to give anything but "the black spot." I have fancied that it reflects something of the 3in. waves.

Refracting Prism and Lens.

A block of paraffin about a cubic foot in volume is cast into the shape of a prism with angles 75deg., 60deg., and 45deg. Using the large angle, the rays are refracted into the receiving hat (Fig. 21), and produce an effect much larger than when the prism is removed.

a third grid, with its wires at 45deg. between two crossed grids, restores some of the obliterated effect.

Radiation reflected from a grid is strongly polarised in a plane normal, of course, to that of the radiation which gets through it. They are thus analogous in their effect to Nicols, or to a pile of plates.

The electric vibrations which get through these grids are at right angles to the wires. Vibrations parallel to the wires are reflected or absorbed.

Reflecting Paraffin Surface.

To demonstrate that the so-called plane of polarisation of the radiation transmitted by a grid is at right angles to the electric vibration,* *i.e.*, that when light is reflected from the boundary of a transparent substance at the polarising angle the electric vibrations of the reflected beam are perpendicular to the plane of reflection, I use the same paraffin prism as before; but this time I use its largest face as a reflector, and set it at something near the polarising angle. When the line of wires is parallel to the plane of incidence, in which case the electric vibrations are perpendicular to the plane of incidence, plenty of radiation is reflected by the paraffin face. Turning the grid so that the electric vibrations are in

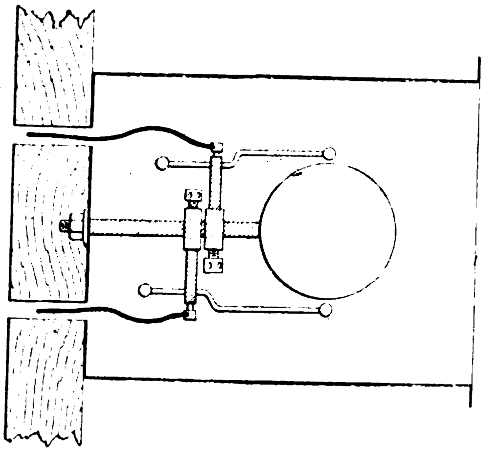


Fig. 20.—Spherical Radiator for emitting a Horizontal Beam, arranged inside a Copper Hat, fixed against the inside of a Wooden Box. One-eighth natural size. The wires pass out through glass tubes not shown.

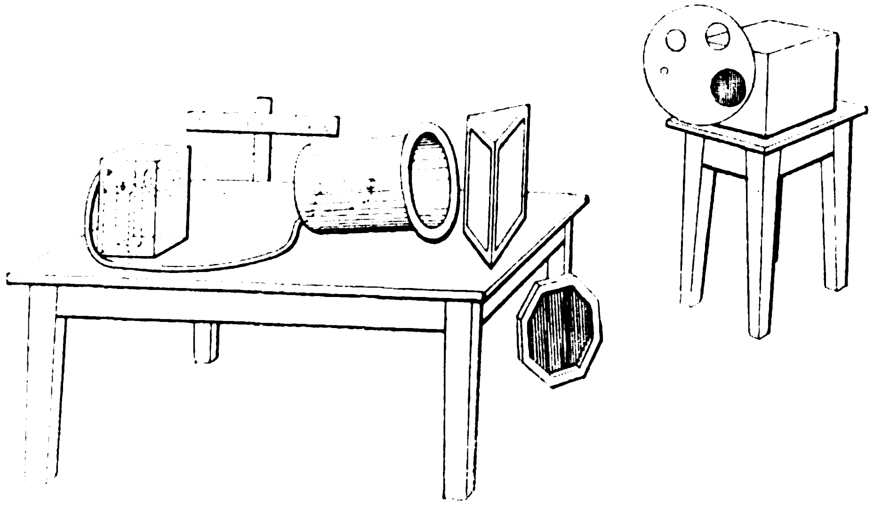

Fig. 21.—General arrangement of experiments with the Copper "Hat," showing Wooden Box on a Stool, inside which the Radiators were fixed; the Copper Hat containing the Coherer; the Metal Box containing Battery and Galvanometer Coil; a Paraffin Prism; and a Polarising Grid.

An ordinary 9in. glass lens is next placed near the source, and by means of the light of a taper it is focussed between source and receiver. The lens is seen to increase the effect.

Arago Disc; Grating and Zone-plate.

The lens helps us to set correctly an 18in. circular copper disc in position for showing the bright diffraction spot. Removing the disc the effect is much the same as when it was present. Add the lens and the effect is greater. With a diffraction grating of copper strips 2in. broad and 2in. apart, I have not yet succeeded in getting good results. It is difficult to get sharp nodes and interference effects with these sensitive detectors in a room. I expect to do better when I can try out of doors away from so many reflecting surfaces; indoors it is like trying delicate optical experiments in a small whitewashed chamber well supplied with looking-glasses; nor have I ever succeeded in getting clear concentration with this zone-plate having Newton rings fixed to it in tinfoil. But really there is nothing of much interest now in diffraction effects except the demonstration of the waves and the measure of their length. There was immense interest in Hertz's time, because then the wave character of the radiation had to be proved, but every possible kind of wave must give interference and diffraction effects, and their theory is, so to say, worked out. More interest attaches to polarisation, double refraction, and dispersion experiments.

Polarising and Analysing Grids.

Polarisation experiments are easy enough. Radiation from a sphere is already strongly polarised, and the tube acts as a partial analyser, responding much more vigorously when its length is parallel to the line of sparks than when they are crossed; but a convenient extra polariser is a grid of wires something like what was used by Hertz, only on a much smaller scale; say an 18in. octagonal frame of copper strip with a harp of parallel copper wires (*see* Fig. 21). The spark-line of the radiator being set at 45deg., a vertical grid placed over receiver reduces the deflection to about one-half, and a crossed grid over the source reduces it to nearly nothing.

Rotating either grid a little rapidly increases the effect, which becomes a maximum when they are parallel. The interposition of

the plane of incidence, we find that the paraffin surface set at the proper angle is able to reflect hardly anything. In other words, the vibrations contemplated by Fresnel are the electric vibrations; those dealt with by McCullagh are the magnetic ones.

Thus are some of the surmises of genius verified and made obvious to the wayfaring man.

A NEW PHENOMENON OBSERVED IN THE PASSAGE OF ELECTRICITY THROUGH BADLY CONDUCTING LIQUIDS.†

BY O. LEHMANN.

During the electrolysis of good liquid conductors the changes are known to be confined to the proximity of the electrodes. As far as I know, no changes have hitherto been observed in the interior of badly conducting liquids (if we disregard convection currents and electric osmosis). On the other hand, I have found the passage of electricity through various badly conducting solutions, especially of aniline dyes, to be attended by changes propagated quickly and continuously from the electrodes to the centre, and, finally, by the formation of a precipitate in the middle of the liquid, or at least between the electrodes. The phenomena are most easily observed by means of a microscope and an arrangement previously‡ described.

If, for instance, a current of about 70 volts pressure is conducted through an aqueous solution of Congo red, a pretty sharply marked halo is formed round both electrodes of a beautiful blue colour at the anode and somewhat paler than the rest of the solution at the cathode, but divided off from it by a darker boundary (Fig. 1).

* *Cf.* Trouton, in *Nature*, Vol. XXXIX., p. 393; and many optical experiments by Mr. Trouton, Vol. XL., p. 393.

† *Wiedemann's Annalen*, Vol. LII., No. 7, 1894.

‡ O. Lehmann, "Molecular Physik, 1," p. 834, 1888.

Digitized by Google

The two halos extend rapidly, and finally meet in the middle. As soon as this happens a *dark blue pigment precipitate* is produced there on the side of the anode, while towards the cathode the solution becomes *colourless*, both phenomena taking place in the small zone where the halos meet, while the rest of the solution remains unaltered (Fig. 2).

At the same time the liquid shows great disturbance where the dark blue and the colourless strata meet, while the rest remains perfectly still. An E.M.F. of a single secondary cell suffices to produce the halos, but their advance is more rapid the higher the E.M.F. When the latter is too high, the observations are impeded by the quantity of gas bubbles appearing at the electrodes.

The experiment is made more covenient by thickening the solution with gelatine, sugar, or glycerine. It is then easy to prove that the extension of the halos is not due to a flow of the liquid, for even with a rapid extension suspended particles of dust and air bubbles remain almost perfectly stationary, so that we can only have to deal with a rapidly advancing constitutional change in the liquid. At the same time it may be observed that the rapidity of expansion of the halos is inversely proportional to the viscosity of the solution. If the expansion is to be observed in very viscous solutions the E.M.F. must be correspondingly increased. The boundaries then become serrated, and the divisions are the finer the higher the E.M.F. By dissolving the pigment in glycerine, and saturating the warm solution with sugar, solutions can be produced of such viscosity that even with 10,000 volts the rate of expansion is not greater than it is with a few volts in an aqueous solution.

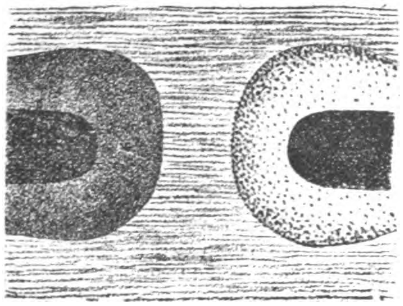

Fig. 1.

Now, as regards the explanation of the phenomenon, one might think of a kind of electric osmosis in the capillary layer between the object carrier and the cover-glass of the microscope; but this is contradicted by the fact that no motion of the liquid itself is visible, but only a progressive change of colour. It can also easily be proved that the migration takes place in the same way in the absence of the walls of the vessel, by immersing two platinum wire electrodes in a larger glass vessel filled with the solution, as in the usual demonstration of electrolysis. If water is the solvent, the convection currents produced by the heating of the solution will indeed disturb the regular expansion of the halos ; but these currents may be obviated by adding to the solution sufficient gelatine to make it form a loose jelly. Even in a perfectly free-coloured gelatine block not enclosed in a vessel the migration of the halos and the formation of the precipitate at their junction may be observed without a magnifier, with any distance between the electrodes. With a very loose jelly, and 90mm. distance between the electrodes, for instance, the halos met nearly half way between the electrodes 10 minutes after the current had commenced to pass. At the place where they met a precipitate was formed, attended by violent commotion in the interior of the mass ; but soon the precipitate was redissolved, and in consequence of the strong heating the gelatine at that point was liquefied. Measured by a thermometer, the temperature was uniformly 24°C. between the electrodes and the centre ; *i.e.*, in the narrow space where the halos met the temperature was 32deg., which accounts for the liquefaction of the mass at that point. The rapid movements and the striking increase of temperature at the centre of the mass show that there the greatest amount of work is done by the current, so that there also a relatively high fall of potential must take place.

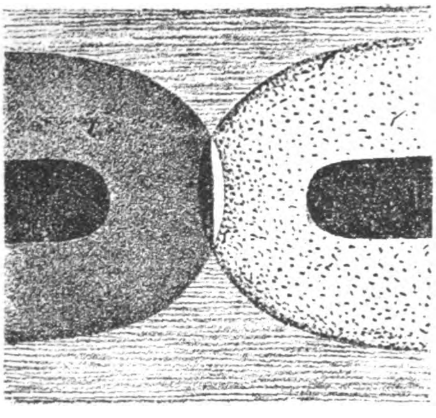

Fig. 2.

A clue to the explanation of the phenomenon is given by the changes of colour, which indicate that the products of electrolysis appearing at the electrode (especially oxygen and hydrogen) have something to do with the formation of the halos. The extension of the boundaries points to the conclusion that these products of decomposition diffuse with a relatively high speed in the direction of the current, and the occurrence of a considerable fall of potential at the boundary of the two halos proves that the diffusing particles carry strong electric charges of the same sign as their electrodes. Thus we may take the following view of the nature of the phenomenon. The dissociated molecules appearing at the electrodes are given charges of the same sign by contact with them, and approach each other along the lines of force, due to the fall of potential in the liquid, until they encounter molecules, with which they combine chemically. New molecules of the dissociation products follow, and reach greater distances from the electrodes until they are also chemically bound. Thus the solution will be chemically changed near the electrodes for constantly increasing distances, producing steadily expanding halos of different colour. When their edges meet the same phenomena take place as are seen when the electrodes are moved very close together ; *i.e.*, convective electric discharges take place, with turbulent motions in the liquid.

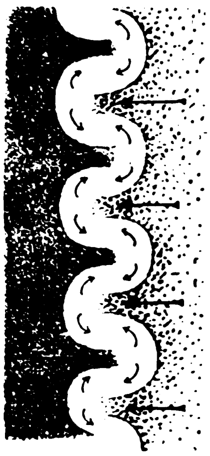

Fig. 3.

Observations of the nature of these currents appear, in fact, to corroborate this view. Fig. 3 shows the course they take before they are disturbed by the formation of the pigment precipitate. Each of the two electric surfaces acquires a wavy outline, the crests of the waves get sharper and send out jets of liquid into the corresponding hollows of the opposite surface. This is accompanied, firstly, by a neutralisation of the opposite chemical changes of the two liquid portions, and a regeneration of the original pigment with development of heat ; and, secondly, by a separation of the electrified particles of pigment from the oppositely electrified solution, so that the pigment particles are accumulated towards the electrode as a precipitate, while the colourless solvent occupies the other half of the mixed region.

While in the above we have only spoken of solutions of Congo red it is not to be supposed that this is the only solution showing the phenomenon in question. The examination of a large number of other solutions gave precisely corresponding results, sometimes with very interesting details. The following gelatinous aqueous solutions were especially noteworthy, the colours of the halos proceeding from the electrodes being given in brackets :—Marine blue (blue—violet), saffranin (red—violet), chrysoidin (reddish yellow—brownish yellow), tropeolin (violet—reddish yellow), Bordeaux red (brick red—blue), eosin (yellow—bluish red), malachite green (colourless—bluish green). In every case the experiments also succeed on the larger scale.

When a current of 70 volts pressure was conducted through a layer of gelatine a few millimetres thick, spread over a sheet of glass and coloured with malachite green, the electrodes being 99mm. apart, hilly elevations were formed round both electrodes, which extended with the migration of the halos and met in about thirty minutes at a distance of 55mm. from the anode. The boundary of the elevation round the anode was perfectly round,

Digitized by Google

and its colour a bluish-green; the elevation round the negative electrode was colourless and showed radiating projections recalling a positive Lichtenberg figure. At the junction of the two elevations a dark green precipitate appeared towards the cathode, a narrow colourless zone towards the anode. Over the dark green precipitate the gelatine rose as if strongly attracted towards the cathode; whereas the colourless zone was more and more depressed, and finally disappeared entirely, so that the glass plate was laid bare and the current interrupted. These expansion phenomena of the gelatine are doubtless connected with the chemical changes in the liquid, and are exhibited in the same manner in the case of other pigments. They resemble experiments by E. du Bois-Reymond with coagulated albumen, which have not hitherto been explained in detail.

Besides the solutions mentioned, numerous others were examined with varying success. Specially suitable for the study of the vortex phenomena at the meeting of the halos was a solution of methyl violet charged with sugar. Other thickening substances, instead of gelatine, sugar, and glycerine, were gum arabic, dextrin, barley sugar, inulin, emulsin, and starch paste, some of which were fairly successful.

Water could also be replaced by other solvents. Very fine experiments were made, for instance, with solutions of Congo red in glycerine, methyl blue in propyl alcohol, phenyl blue in chinoline (yellow-white), and methyl blue in aniline, with a little alcohol. Whether colourless solutions also show the phenomenon is difficult to say, since the migration of the halos is only indicated by changes of colour, not by the formation of stripes, &c. In solutions provided with fine dust particles, a jerky motion of these is often observed where the edge of a halo passes such a particle, as if they were attracted by the approaching halo and then were once more quiet. By such a motion of small suspended particles of lamp-black or inulin I could recognise, for instance, the progress of halos and the occurrence of vortex motions in an aqueous solution of amygdalin.

By filling a liquid with numerous small particles the migration of the halos may be observed by means of changes in their density of distribution with nearly the same ease as by the employment of pigments. Specially well suited to this purpose is the commercial liquid Indian ink (E. Wolff and Son) strongly diluted with water and thickened by adding a little sugar or glycerine. This (pseudo) solution is highly sensitive to various foreign admixtures; mere traces of salts, pigments, &c., precipitate the carbon in a flocculent form, usually in conjunction with the precipitating body; while other bodies, even if highly concentrated, have no influence upon the distribution of the carbon particles. It is probably this property of the liquid Indian ink which specially adapts it to the purpose of recognising the advance of the halos. This is in accordance with the fact that thickening substances like sugar and glycerine, which hinder sedimentation, also impede electric sedimentation. Besides Indian ink, some other commercial tube pigments are suitable, such as carmine, Berlin blue, &c. But the phenomena are complicated by the well-known migration of such powders to one pole, by the distribution of the particles along the line of force, and their conglomeration into small heaps acting as secondary electrodes. The phenomena are beautifully shown by means of the pigments supplied by Th. Günzberg, of Würzburg, especially Indian ink, Berlin blue, cadmium yellow, crimson lake and Florentine lake, dissolved in acetal. The migration of the powders also exhibits well under the microscope the species of motion in the liquid during convective discharge, about which more will be said on another occasion.

LIGHTING BY RESONANCE.*

In describing Dr. Pupin's system of "resonating conductors" and its application to telegraphy and telephony in our issue of May 23rd, reference was made to the fact that Dr. Pupin also contemplated the utilisation of this method for the production of light. As a matter of fact Dr. Pupin has for some time past devoted his attention to this subject, and has progressed sufficiently to encourage him in the belief that at no distant time practical results will be obtained. At the invitation of Dr. Pupin a small party of gentlemen gathered at Columbia College on the evening of May 30th to witness some experiments on the production of light by resonance effects.

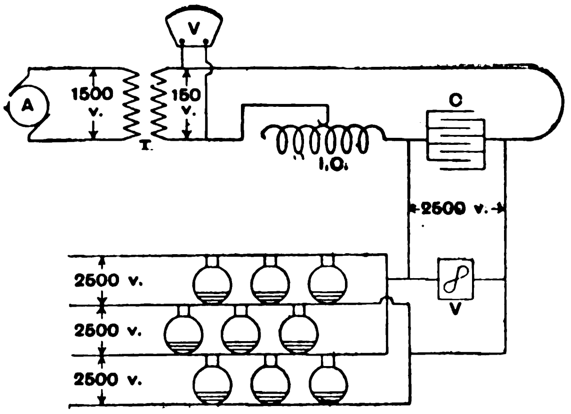
Before passing to the description of these experiments, it may be well to point out briefly that Dr. Pupin has started out with the object of obtaining light effects at low frequencies and comparatively low potentials, having in view the utilisation of existing alternating circuits. By creating resonance effects, Dr. Pupin increases the potential at the lamp terminals so as to produce luminous effects in vacuum tubes.

* From the *Electrical Engineer* of New York.

The experiments showed how it was a simple matter to operate practically any number of vacuum tubes or lamps in parallel, and for that purpose Dr. Pupin employed 100 Edison 100 c.p. lamps. These were used merely for convenience, as a sufficient number of vacuum tubes without filaments was not available. From what follows it is evident that the filaments played no part in the phenomena of light production.

The arrangement of the apparatus employed is shown diagramatically in the accompanying engraving. A 1,500-volt Slattery alternator, A, of the usual type, giving 130 cycles per second, furnished current for a transformer, T, which reduced the pressure to 150 volts at the secondary terminals. In series with the secondary were two inductance coils indicated at I C, one of which could be regulated by throwing sections of the coil in or out. Included in the circuit, also in series, were two condensers, C, of $\frac{1}{2}$ microfarad each.

The lamps, L, were connected as a shunt to the condensers, as shown and arranged in three rows of 33 each, all being connected in parallel across the circuit. Each lamp (100 c.p. Edison) was connected to one side of the circuit by the metal base, and connection to the other side of the circuit was effected through the medium of a tinfoil coating at the bottom of the globe, which covered about one-sixth of the surface of the lamp. A Weston voltmeter, V, measured the potential at the terminals of the transformer secondary, and an electrostatic voltmeter, E S V, measured the potential at the lamp terminals.



Dr. Pupin's Resonance Circuit for Lighting.

The alternator being started, the circuit was turned by means of the adjustable inductance coil, the potential at the lamps gradually increasing up to 2,500 volts, at which the maximum potential was obtained. The glow of the lamps gradually increased in the same manner, and maintained their intensity as long as the coil was allowed to remain at the point of resonance. During all the variations of potential on the lamp circuit while the turning was in progress, and after resonance had been obtained, the voltmeter, V, connected to the secondary terminals showed invariably 150 volts, indicating that the rise in potential at the lamp terminals was due entirely to resonance effects.

As it was Dr. Pupin's sole object to show that glow effects could be obtained from circuits at ordinary commercial frequencies no attempt was made to bring the lamps up to a high degree of luminosity; but, as Dr. Pupin stated, the raising of the frequency to only 1,000 periods per second, which is well within commercial limits, would have brought out a greatly-increased luminosity, while at the same time cutting down the capacity of the condensers required to nearly $\frac{1}{64}$th of that employed by him in the experiment.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, June 22nd.

PHYSICAL SOCIETY.

5 p.m. (1) An Exhibition of Photographs of Flames, by Capt. Abney; (2) "An Elementary Theory of Planimeters," by Prof. Henrici; (3) "The Hatchet Planimeter," by F. W. Hill; (4) "A New Integrating Apparatus," by A. Sharp. Other Papers if time allows.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

University Intelligence.—The University of Cambridge has offered, and will shortly confer, its degree of D.Sc. upon Prof. Demetri Ivanovitch Mendelejef.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing, and Printing Offices:

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d. post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free. Also in German, 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

In Preparation. Very fully illustrated.

ELECTRIC LAMPS AND ELECTRIC LIGHTING.

Being Four Lectures delivered in April-May, 1894, before the Royal Institution, by Prof. J. A. FLEMING, M.A., D.Sc., F.R.S.

NOW READY.

Volume XXXII. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad, carriage extra.
Cases for binding Volume XXXII., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; and Mr. Alexander Siemens, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

ELECTRICITY IN THE KITCHEN.

Many a cautious consumer of electrical energy has wired all the rooms in his house except the kitchen and those necessary parts of the messuage which are known as "offices." The reason is simple; these rooms generally require more artificial light than others, and in order to save trouble, it seems to be an almost invariable practice among servants to light up all or nearly all the gas burners before getting the breakfast ready, and not to give them another thought until bed-time. Automatic switches can be used in connection with the doors of cellars, larders, and cupboards, but even a fifteen-minute or half-hour switch would defeat its own purpose if applied to a glow lamp, for it would be always used, if at all, to its full period, and would be very unpopular. A separate meter is the only check on extravagant consumption in the "offices," a consumption which sometimes exceeds one half of the total. But serious proposals are now being made to introduce electrical supply into the kitchen for a very different purpose, and no exhibition or conversazione is complete without a demonstration of electrical cooking, coffee-grinding, knife-cleaning, and other domestic operations, such as ironing. Leaving, then, the weighty questions of science and engineering, which claim so large a share of our attention, let us give some consideration to this new branch of industry. Hitherto the use of electrical tea-kettles has been a mere novelty, and electric ovens a curiosity, if for no other reason than their costliness; but by degrees prices are becoming more reasonable, probably on account of improvement in the manufacture rather than any considerable increase in quantities made. It is only natural that in its early stages the details of the

Digitized by Google

construction of these appliances should be kept more or less secret. The craft of working in enamels and cements has always been surrounded with mystery, and the completed article is not easy to imitate, because inspection of it gives little or no clue to the process of manufacture. At one time there was a mystery about dynamos and transformers; but it is now quite the exception to find a maker who declines to allow a scale drawing to be published.

If an electric kettle or frying-pan still costs four or five times as much as one of the ordinary make, supply companies are doing their best to popularise such things by offering to provide current at a specially low rate. The idea is that they may be used during the day time, and thus help to increase the day load. Careful experiments in one instance have shown that for general cooking, other than boiling, the electrical system may be actually cheaper; and it is not unlikely that with careful management the electric oven may prove to be of considerable value. Since "science is measurement," and electrical engineers profess to be more or less scientific, some data as to cost are likely to be forthcoming before long. As far as the quality of the cooking is concerned, the new method is, of course, unimpeachable, and although we understand that some gas ovens are practically faultless in skilled hands, it is well known that a little carelessness with the burners, the taps, or the ventilation brings about most objectionable results. A classical test of a gas oven, by a committee of the Gas Institute, records that "a roast leg of mutton, 7lb. 7½oz.; two soles grilled, 1lb. 14oz.; rice pudding, rhubarb tart, puff pastry, and 5lb. roasted potatoes," were cooked by the consumption of only 25 cubic feet of gas; and "the whole of the cooking was very well done." Against this we have the solitary information that an oven of unrecorded cooking capacity was heated in a quarter of an hour to 350°F., taking 25 amperes, or rather more than half a supply unit. This amount of energy is offered by more than one company, for cooking or other day work for 2d., and when it is considered that 25 cubic feet of gas at 3s. costs only 0·9d., it seems that electrical cooking is out of the running. It is certainly severely handicapped, but in a long enough race it will win, and for the following reason:—A gas oven must be thoroughly and continuously ventilated, or the consequences are disastrous; and the gas, though not blazing away full on all the time, has to maintain the draught and uselessly heat the wasted air. The electric oven, on the other hand, can be kept almost closed, and can be so well lagged that four or five amperes will suffice to keep up the full temperature. A difficulty in the way of cooking, either by gas or by electricity, is that a hot water service is provided in all modern houses, and nothing but a coal fire will maintain the circulation with economy. In a large house it may be worth while to put in a special boiler; but as a rule the fire must be kept in, and being kept in, it must be an important factor in the question of daily cooking. Since an electric oven needs no special ventilation or arrangement, it ought to be easy to fit up an existing range with electric heating plates, and thus avoid not only the expense of a new and complete oven, but of the room that it would occupy, and of the current required for the preliminary heating.

Passing by the important problems concerning frying-pans, saucepans, and grills, the teapot and coffee-pot deserve a word. We have never heard of a gas-boiled kettle in a lady's drawing-room, though it is common enough in a bachelor's chambers. Competition, if it is worth mentioning, is with the spirit lamp. To boil water for tea on a small scale electrically, costs, we believe, one-sixth of a penny, probably twice as much as with the impossible gas burner. The convenience makes it well worth while, but the first cost of the kettle is a serious obstacle. A little hot-plate can be bought for about £1, and any flat-bottomed kettle can be used with it, at a rather lower efficiency. The electric kettle is a very efficient piece of apparatus, since the heat is generated where it is wanted; but a still more efficient one, which would have several conveniences, would be a boiling stick, to be plunged into the water like a red-hot poker. Such things have been made, but nothing has been heard of them. A silver tube with double walls, containing between them a resistance of about 14 ohms, ought to boil a pint of water in five minutes; free circulation through the middle of the tube would give a large heating surface. Such a boiling appliance could be put into a tea kettle or coffee pot, or anything else; the heat would not have to force its way through the bottom, but would be generated in the middle of the work. As in many cases of household economy, a small increase of actual cost, if accompanied by a great reduction of labour, more than justifies itself. Some occupations, such as cooking by a coal fire, are so unpleasant that menial services are commonly confounded with mean services; nor is the use of gas stoves much better, for while the interior has to be carefully ventilated this is often done at the expense of the rest of the house, which reeks of acetylene, carbonic oxide, sulphurous acid, and other "by-products"; with electrical cooking the odours of the food and nothing else have to be got rid of. The vast increase of machinery and inventions contribute very little to ease, comfort, and well-being, the general tendency is to increase the luxury of the luxurious with but little diminution of the drudgery of drudges. A revival of the art of cookery seems to be spreading, and newspapers open their columns to recipes, few of which probably descend to the kitchen unless as waste paper. Remove the disagreeables of cooking, and the reader of the *Daily Telegraph* will be able to spread open his paper on his mahogany sideboard and compound his own *bouillabaisse* according to the latest leading article thereon, the devotee of the *Westminster Gazette* will bend over his Irish stew, and, *fin de siècle*, the subscriber to the *Pall Mall Gazette* will prepare with cultured hands among his books and household gods, with suitable ecstatic exclamations, the onion soup of his last Saturday's number. But judging from painful experience at electrically-cooked dinners, where for the novelty of the thing the cooking was done in the dining-room, it must be remembered that the delectable leek and the savoury cutlet will ever exhale their native odours; and to even the most poetic of us, a cooking apparatus by the table's brim a cooking apparatus it must always be to him. And this bringing us to dinners, we must refer to the numerous and influential company which assembled last Friday evening at the Cannon-street Hotel, by invitation of the Chairman and Directors of the City of London Electric Lighting Company. An electrically-cooked banquet was the chief attraction of the evening, and after the company had dined Sir David Salomons informed his guests that "the cost per head was twopence per ten courses, and, consequently, the actual cost of each guest that evening was threepence." This sounds cheaper even than a vegetarian dinner; but the Chairman only referred, of course, to the price of the electrical energy consumed in the cooking. The cost of the food was modestly suppressed. The Chairman further announced that, on coming to the dinner that evening, he found that the ovens erected for the occasion were capable of providing for 120 guests, and consumed 60 units. Each guest, therefore, had the satisfaction of knowing that he had consumed the thermal equivalent of 500 watt-hours, less losses from radiation, convection, and conduction.

REVIEWS.

A Short Practical Treatise on Municipal Electric Lighting. By Francis Hastings Medhurst, B.Sc. M.I.E.E. (London: J. J. Keliher and Co.)

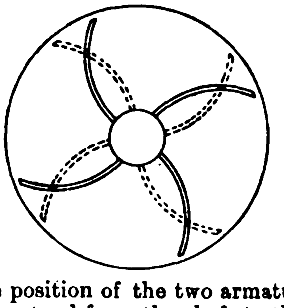
If journals specially devoted to his enlightment, popularly written guides, and a grand army of consulting electrical engineers, do not keep the town councillor in the way he should go in the matter of electric lighting, it is evident that he must be suffering from a double dose of original sin. Mr. Medhurst's contribution to the town councilor branch of electrical literature runs to a length of 125 demy-octavo pages, some hundred of which are taken up by reprints of the Electric Lighting Acts, a Deed of Provisional Order Transfer from a Corporation to a Company, and the Weston-super-Mare Electric Lighting Order. The author's introduction to these documents is a plea for municipalisation, with its useful and necessary accompaniment of work for competent consulting engineers. Printed matter intended for general consumption cannot, we fully recognise, be expected to be mathematically accurate; nevertheless, when out of ten metropolitan supply companies only six are as yet dividend-paying concerns, and the sums set aside for depreciation, &c., are mostly extremely modest, why give the reader to understand that the dividends range between 4½ per cent. and 7½ per cent., and that considerable sums have been set aside? The profits at Bradford we are also told have enabled the Corporation to reduce the rates; a rather wonderful feat to perform out of a total net profit up to June last year of under £1,000. On page 8 the author tells us that it cannot be denied that one of the reasons why electric lighting has been more universally adopted in Germany, in France and in America than in England is the "unreasonable" opposition of the gas companies. In the United States there is undoubtedly more electric lighting than here, but scarcely less opposition from the gas interest. In France there is less electric lighting than in England and considerably more opposition from the gas interest. In Germany there is probably just as much of both as in England. This opposition may be mistaken; it is certainly not "unreasonable," and where gas is dear and electricity is cheap it can be disregarded. It is not the difference in the gas opposition which causes the difference in the relative *vogue* of electric lighting in various countries, but mainly the difference in price. Town councillors may like to orate about "unreasonable opposition" and "effects prejudicial to the general community," but if electrical engineers had once tasted the sweets of 10 per cent. and 12 per cent. dividends we doubt if even they would embrace with open arms a formidable rival.

AN OPTICAL PHASE INDICATOR AND SYNCHRONIZER.*

BY GEORGE S. MOLER AND FREDERICK BEDELL.

Various devices have been employed to indicate synchronism and to show when an alternate current motor is in opposite phase to the generator, one of the simplest of these devices consisting of an incandescent lamp used as a pilot lamp. This device does not, however, indicate the moment when exact synchronism is reached, nor does it show whether the motor is running at a greater or less speed than that corresponding to the generator. It does not show the exact phase difference between the motor and generator, and does not indicate the phase relations after the motor has been connected to the alternator and is being driven by it. The following instrument has been devised by the writers to give definite information in regard to the relative speeds and phase positions of the motor and generator in laboratory investigation.

The motor and generator are placed together with shafts in line and abutting, but not quite touching. The two machines must have the same number of poles, so that a revolution of the armature of each represents the same number of alternations. The abutting ends of the shafts carry two discs. In these discs are curved slits, one slit for each pair of poles of the machines. The two discs are in every way similar, the one being the reverse of the other. The curvature of the slits is such that the distance to or from the centre that the intersections of the two sets of slits move is proportional to the change in relative position of the two armatures. When the two armatures are running at the same speed in the same direction and there is a source of light on one side of the discs, the intersection of the slits, as seen from the other side, appears as a continuous ring of light. A slight difference of speed causes this ring of light to move outward or inward, according to which disc is revolving the faster. The position of the ring of light



indicates the relative position of the two armatures. A stationary scale is fixed so as to extend from the shaft to the edge of the discs on the opposite side from the lamps, so that the distance of the changing line of light from the centre may be read so as to give the phase difference of the two machines by direct reading. To enable one to see the scale and line of light most conveniently, a mirror is arranged at 45 deg. with the discs, and a glow-lamp and screen of oiled paper is placed behind them.

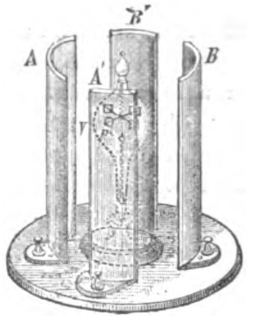
* Abstract of a paper read before the Philadelphia meeting of the American Institute of Electrical Engineers, May 17, 1894.

ELECTROSTATIC ROTATIONS IN RAREFIED GASES.

BY RICCARDO ARNÒ.

Crookes found that a rarefied gas, through which an electric discharge is passed by means of two electrodes, exercises upon a small mill-wheel resembling that used in a radiometer certain actions which, if the various parts of the apparatus are suitably disposed, have the effect of producing a continuous rotation of the mill-wheel, as it would take place if its vanes were driven from the cathode to the anode.*

The object of the present note is to describe certain experiments which show that a phenomenon of the same kind may be obtained by subjecting the rarefied gas in which the mill-wheel is immersed to the action of a rotating electric field.



The method previously employed† has also been used for obtaining the rotating field necessary for these experiments, being based upon a simple alternate difference of potential between two fixed points, represented by the extremities of the secondary coil of a large Rhumkorff coil without a commutator, acting like an ordinary alternate current transformer.

To exhibit the new phenomenon referred to, it is not advisable to employ the ordinary radiometers with mica vanes, since even when these are surrounded by gas at ordinary pressure, forces act upon them which are due to the action of the rotating electric field upon the mica.‡ I therefore had recourse to an apparatus specially constructed for the experiments, consisting of a mill-wheel, *m*, with four very delicate brass vanes mounted in a glass bulb, V, containing very highly rarefied air. It was in fact only by working with a completely metallic mill-wheel that I could make sure of having eliminated all direct action of the rotating field upon the vanes of the wheel, and of ascertaining the new effects due to the presence of the rarefied gas.

If the apparatus described is introduced between two pairs of copper strips, A B and A′ B′, arranged crosswise and enclosing

* *Phil. Trans.*, 1879, I., p. 152.

† *Rendiconti dei Lincei*, October 16, 1892, p. 284; *The Electrician*, Vol. XXX., p. 516, March 3, 1893.

‡ It has in fact been proved, in the paper quoted above, that a dielectric placed in a rotating electric field is subjected to a couple tending to make it rotate in the direction of the field itself.

Digitized by Google

the rotating electric field, and the field intensity is great enough and the bulb well dried, it is observed that the brass vanes commence to rotate in the same direction as the field itself. And if the field is reversed while the vanes are turning in one direction, the metallic wheel is rapidly brought to a standstill, and then commences to rotate in the opposite direction.

In my experiments, performed with an alternating current of frequency 40 and a distance of 15cm. between the strips, the effective difference of potential between the terminals of the secondary wire of the induction coil was about 7,500 volts. Under these conditions, corresponding to an electric field rotating with a velocity of 40 turns per second and having an intensity of 1·67 C.G.S. electrostatic units, the metallic wheel acquired a velocity of 50 turns per minute.

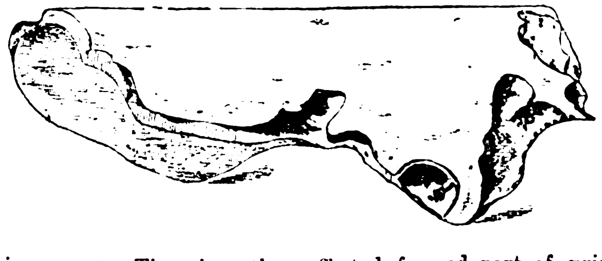
I have said that, to exhibit the new phenomenon described, the experiments must be conducted with wheels with conducting vanes. I must add that this condition, necessary in order to avoid the direct action of the rotating electric field upon the wheel, is also sufficient. Suitable experiments have, indeed, shown me that, whilst in air under ordinary pressure four mica vanes arranged crosswise rotate with the field like all dielectrics, there was not the slightest couple exerted upon an entirely metallic wheel. Such a wheel, even when suspended in a very intense rotating field by a very fine and long silk thread, remained fixed in the field.

It should be mentioned that under the conditions of my experiments, the action of the rotating field upon the rarefied gas was such as to illuminate uniformly the interior of the glass bulb, in such a manner that, even when working in total darkness, the rotating wheel could be distinguished well enough to count the number of revolutions.

It follows from the results specified that the cause of the phenomenon must be looked for in forces developed inside the bulb, which are indirectly excited by a special action exercised by the rotating field upon the rarefied gas. It would be, in fact, owing to this action that the gaseous molecules contained in the glass bulb are, under the influence of the rotating field, influenced by forces tending to drag the molecules themselves along with the rotation of the field. The air enclosed in the apparatus is in such a condition of rarefaction that the paths described by each molecule, in the interval comprised between two successive encounters with its neighbours, are not, as in gases under ordinary pressures, extremely short. It is therefore clear that the gaseous molecules under the influence of the electric field can in their turn act upon the metallic vanes of the wheel, and generate within the bulb a couple tending to make the wheel rotate in the direction of the field itself.

THE CORROSION OF CAST-IRON WATER MAINS.*

A somewhat peculiar case of external corrosion of two cast-iron water mains has recently come under our notice, and will no doubt interest a number of our readers. It is a case in which results very similar to those which are now so frequently ascribed to wandering electric currents, that it receives additional interest



in this respect. The pipes thus affected formed part of private service mains in the neighbourhood of the Strand, and consisted of two separate 4in. main pipes in 9ft. lengths, running side by side, and placed at a depth of some 3ft. below the level of the ground. The mains, which were laid some twelve years ago, were surrounded chiefly by gravel and clay; but the portions at which the corrosive actions took place exclusively were embedded in cinders. The annexed sketch portrays the character of the wasting or pitting, and it will be observed that the holes would almost appear to have been gouged out. This, however, is disproved by the number of lengths affected, namely, six. The defective portions were discovered owing to the pipes having in some cases become so much reduced in thickness as to be unable to withstand the pressure within them. We have ascertained that there are no electric mains in the neighbourhood of the pipes, so that this phenomenon cannot have been produced by short circuiting or earthing. The crown plates of steam boilers, upon which ashes have been employed as a non-conducting material, have been known to suffer in a very similar manner where any moisture has been allowed to collect. Numerous experiences of this kind might be mentioned, and the partial conversion of the affected parts into plumbago have been also known, and it is quite possible some of those now ascribed to electrolytic action may be due to similar causes.

* From the *Engineer*.

ELECTRICAL TRANSMISSION OF POWER WITH DI-PHASE CURRENTS FOR MINING PURPOSES.*

One of the most interesting cases of the electrical transmission of power for coal-mining purposes in Europe has been completed and set in operation at the Decize Collieries in the Nièvre Department of France, which are owned by MM. Schneider and Co. This installation is remarkable from the fact that diphase alternating currents are employed for the transmission, and diphase alternating-current motors are used for reconverting the electrical energy into mechanical power at the different pits. A brief outline of the principal features of this plant should prove of special interest to English readers, more particularly as no installation of this nature has yet been put down in the United Kingdom. In designing this plant the problem to be solved was to erect a central generating station for the distribution of electrical energy at the different pits, where it could be utilised in electromotors for operating ventilating fans, hauling machinery, pumps and for lighting purposes. A general idea of what had to be accomplished is shown in the annexed table :—

Site.	Distance from generating station.	Electrical machinery or lamps receiving the current transmitted.
1.—*West.*	Yards.	
Puits des Chagnats ...	5,090	30-H.P. electric motor.*
Fendue des Lacets ...	3,466	" " *
Puits des Coupes	2,058	" " *

Champvert	3,250	12-H.P. power electric motor.‖

* Used for ventilating fan. † Inclined plane. ‡ Lighting. § Ventilating fan and lighting. ‖ Pumping.

The generating station is situated respectively at distances of from 3·1 miles and 1·86 miles from the extreme points which have to be supplied with current. It contains a battery of six boilers and two units (steam engines and dynamos), each of a capacity of 100 kilowatts; a further unit will shortly be laid down. The two units may be worked singly or in parallel. The engines are of the horizontal non-condensing type, running at 200 revolutions per minute, and driving the diphase alternators by means of belting. A notable feature in this connection is the fact that each electrical unit comprises a twin alternator, or in reality two machines, placed one at each end of the shaft, the driving pulley carrying the engine belt being arranged in the middle of the shaft. The generators are Zipernowsky ten-pole alternators, with revolving field magnets. The ten field magnets are connected together in series, and the exciting current is led to them by means of two metallic rings carried on an extension of the driving shaft on the opposite side to that of the driving pulley—that is to say, on an outer extension of the shaft. Two ordinary brass brushes press upon these rings, to which the exciting current is furnished by a direct-current dynamo. This latter machine is operated by a belt from the shaft of the alternator. At 900 revolutions a minute this direct-current dynamo supplies the exciting current for the twin alternator, being between 25 and 30 amperes at 110 volts. The fixed armature of the alternators is formed of ten coils, any one of which can be withdrawn and replaced with little trouble.

The current is transmitted mainly by means of overhead wires to the points of utilisation, the only portion laid underground being towards the end of the principal line leading to the Chagnats Pit. The wires forming the overhead line are of silicon-bronze, and are carried on porcelain insulators attached to poles 24ft. high. The diameter of the wires constituting the principal line to the western part of the district is 6mm., and 4mm. in the case of the remainder of the line. It is noteworthy that the same poles carrying the transmission wires also support telephone wires, the latter being arranged 12ft. from the ground. In order to counteract the effects of induction in the telephone wires, the line

* Abstract from the *Colliery Guardian*.

Digitized by Google

conductors are crossed at distances averaging 540 yards. The small portion of underground line forms a lead-covered cable, laid in a wooden conduit, as also does the telephone line for the same distance. Suitable lightning conductors are provided at the generating and distributing sub-stations and at intervals along the line. The electromotors at the sub-stations, where the current is utilised for the different purposes mentioned in the table given above, are of the same type as the generators. These diphase motors are easily set in operation, and are to all intents and purposes left to themselves for several hours together. The only attention they receive is the visit of an employé every six or eight hours to ascertain whether the motors are working properly. The sub-stations are situated in the forest, and the facility of working on this system as compared with the erection in each place of a boiler, steam-engine and ventilating fan, is considered to be remarkable, apart from the question of the cost of transporting fuel.

TRAMWAYS IN GERMANY: A COMPARISON BETWEEN THE COST OF HORSE TRACTION AND ELECTRIC TRACTION.*

The comparison is founded on many years' experience of an important German tramway company in horse traction (the situation of which, however, is not given), and by carefully-obtained trial-results in electric traction.

The tramway selected is 8·08 miles in length, and establishes intercourse between a large town and several suburbs. The time-table is so prepared that the trams run at 6, 6:30, 7 a.m., and then every quarter of an hour until 9 p.m., after which they run at 9:30, 10, 10:30, and 11 p.m. The car, which is a one-horse one, carries 30 persons inclusive of driver and guard; on 20 days of the year it is necessary to double this service.

With the use of horse traction a speed of 8 to 10 miles an hour is the limit, and 8 cars are required for the service; 126 (2 × 63) single tours are made daily, and 1018·08 (126 × 8·08) car miles are run, consequently 391,961 [(365 + 20) × 1018·08] car miles are run in the year.

As the daily performance of a horse in tramway work amounts on the average to 16 miles, theoretically 63 horses are required for the usual traffic, but in practice 10 per cent. more are added to make allowances for disease and rest, so that 70 horses are kept. The 70 horses represent a capital of £3,150 (70 × £45), and a further sum of £4,250 is required for land and buildings. The following Tables are then given as representing the yearly cost of horse-traction.

I.—*Payment of Interest and Depreciation.*

4 per cent. interest on £7,400 (3,150 + £4,250)	£296	0
15 „ depreciation of capital value of horses	472	10
1½ „ „ „ „ buildings	63	15
Total	£832	5

II.—*Cost of Management.*

Salary of manager	£90	0
Wages of eight drivers	360	0
Wages of six stable-boys	150	0
Provender for seventy horses	2,175	0
Harness and shoeing	287	10
Veterinary treatment	65	0
Repair of stables, &c.	100	0
Sundries	72	10
Total	£3,300	0

These two sums, amounting to £4,132. 5s. yearly for 70 horses, gives 3s. 2·8d. per horse per day. But to this sum is still to be added the hiring price of 63 horses for 20 days at 5s. per day, which amounts to £315. Therefore the total yearly disbursement for horse-traction is £4,447 5s., the cost per car-mile being 2 72d. $\left(\frac{\pounds 4{,}447.\ 5s.}{391{,}961}\right)$.

The estimate for electric traction is founded on the overhead line system of O. L. Kummer & Co., of Dresden. Each car is provided with two electromotors of 8 H.P. The capital required is estimated as follows:—

Land	£150	0
Buildings	1,600	0
Boiler and engine and two dynamos, including all fittings	3,750	0
Length of 8·08 miles of line work, fixed complete	3,500	0
Electric fittings for nine cars, one of which stands in reserve	2,250	0
Total capital expenditure	£11,250	0

* From the *Foreign Abstracts* of the *Proc.* Inst.C.E., Vol. CXVI.

The following tables are then given as representing the yearly cost of electric traction:—

I.—*Payment of Interest and Depreciation.*

4 per cent interest on £11,250	£450	0
1½ „ depreciation on buildings account	24	0
7½ „ „ engine, &c., account	281	5
5 „ „ line work account	175	0
15 „ „ electro-motors account	337	10
Total	£1,267	15

II.—*Cost of Management.*

Salary of manager	£90	0
Wages for three enginemen	180	0
Fuel	830	0
Carriage of Cinders	10	0
Lubricants	125	0
General repairs	225	0
Sundries	72	5
Total	£1,532	5

These two sums, amounting to £2,800, give 1·72d. per car-mile as the cost of electric traction.

The Paper concludes in enumerating several advantages that electrical cars possess over the horse cars in the matter of speed, safety, and size in crowded streets, as well as in cost.

ON THE WHIRLING AND VIBRATION OF SHAFTS.*

BY STANLEY DUNKERLEY.

It is well known that every shaft, however nearly balanced, when driven at a particular speed bends, and, unless the amount of deflection be limited, might even break, although at higher speeds the shaft again runs true. The particular or "critical" speed depends on the manner in which the shaft is supported, its size and modulus of elasticity, and the size, weights and positions of any pulleys it carries.

The theory for the case of an unloaded shaft first received attention at the hands of Prof. Rankine,† who obtained numerical formulæ for the cases of a shaft resting freely on a bearing at each end, and for an overhanging shaft fixed in direction at one end.

The theory has been further extended to the case of a shaft loaded with pulleys by Prof. Reynolds; and the object of this investigation is to apply that theory and so obtain formulæ—and by experiment to verify them—giving the critical speed in terms of the diameter of the shaft, weights of pulleys, &c., in particular cases applicable to the different conditions under which a shaft works.

In many cases, as might naturally be expected, the "period of whirl" of the shaft is merely its natural period of vibration. The two periods are coincident in the case of an unloaded shaft (however supported), and for a loaded shaft on which the pulleys are placed in such positions that they rotate, when the shaft is whirling, in planes perpendicular to the original alignment of the shaft. With pulleys placed in any other positions, when the shaft is whirling, there is a righting moment tending to straighten the shaft, which does not exist when it merely vibrates under the dead weight of the pulleys. Hence, in an unloaded shaft, the period of whirl coincides with the natural period of vibration; but, generally, in a loaded shaft, the period of whirl is less than the natural period of vibration to an extent depending on the size and positions of the pulleys.

If, therefore, the period of disturbance (that is, the period of one revolution) be decreased, the shaft runs true until that period approximates to the natural period of vibration of the shaft under the given conditions. If the shaft now receive any displacement, however slight, a violent agitation is set up, which will be most marked when the period of disturbance and the whirling period coincide. As the period of disturbance is further decreased the agitation becomes less and, at a period of disturbance slightly less than the whirling period of the shaft, the shaft again runs true.

As in the vibration of rods, so in the whirling of shafts there are a series of periods at which the shaft whirls.

Investigation shows that the formulæ obtained by considering the combined effects of the shaft and only one pulley, or the combined effects of two pulleys neglecting the effect of the shaft, are too complicated—even in the simplest cases—for actual use. The only alternative method is to consider the effects of the shaft and each of the pulleys (whatever be their number, position, and size) separately, and so obtain the whirling speed for each on the assumption that all the others are neglected. By means of an empirical formula the whirling speed, taking shaft and pulleys into

* Abstract of a Paper read before the Royal Society.

† Rankine's "Machinery and Millwork," page 549.

Digitized by Google

account, may be calculated from the separately-calculated speeds of whirl.

Unloaded Shaft.—In the case of an unloaded shaft, the whirling speed is given by an equation of the form

$$(w\,\omega^2/g\,\mathrm{E\,I})^{\frac{1}{4}}\,l = a, \quad \ldots \ldots \quad (1)$$

in which

w = weight of shaft (in lbs. per foot run).
g = gravity.
E = Young's Modulus (in lbs. per square foot).
I = geometrical moment of inertia of cross section of shaft about a diameter.
ω = angular velocity of shaft when whirling.
l = length, in feet, of one of the spans, and
a = some numerical coefficient depending on the manner in which the shaft is supported.

By substituting the proper value for the coefficients in equation (1), we obtain the equations

$$\mathrm{N} = b\,d/l^2, \text{ for a solid shaft,} \quad \ldots \ldots \quad (2)$$

and

$$= b\,\sqrt{(d_1^2 + d_2^2)}/l^2, \text{ for a hollow shaft.} \quad \ldots \quad (3)$$

In these equations

N = number of revolutions shaft makes per minute when whirling.
d = diameter of the solid shaft in inches.
d_1, d_2 = the external and internal diameters of the hollow shaft, both in inches, and
b = some numerical coefficient depending on a, and also upon the constants in Equation (1).

For wrought iron or mild steel, $b = 3331a^2$, and for brass, $2222a^2$.

It should be noticed that each span of a continuous shaft supported on bearings placed at equal distances apart whirls independently of the rest.

Loaded Shafts.—The cases for a loaded shaft—as also those for an unloaded one—which have been considered in the investigation, embrace all those which are likely to arise in practice. With a continuous shaft supported on three or more bearings and loaded with a pulley on one of the spans, general equations have been obtained for unequal spans; but the complete investigation has only been extended to the case of equal spans—a relation between the spans which almost invariably exists in actual shafting. The results of the investigation show that however the shaft be supported, the whirling speed due to a single pulley on a light shaft is given by an equation of the form

$$\omega = \theta\,\sqrt{(g\,\mathrm{E\,I}/\mathrm{W}c^3)}, \quad \ldots \ldots \quad (4)$$

in which ω, g, E, I, have the same meanings as in Equation (1), and

W = weight of pulley in lbs.;
c = distance of pulley from nearest bearing in feet; and
θ = some numerical coefficient depending not only upon the manner in which the shaft is supported, but also upon the position of the pulley on the span which carries it and the size of the pulley.

For any particular mode of support of the shaft the coefficient θ is some function of the ratios c/l and c/k, where l = length of span which carries the pulley, and $k = \sqrt{g\,(\mathrm{A} - \mathrm{B})/\mathrm{W}}$, where A and B are the moments of inertia of the pulley about the axis of the shaft and a diameter of the pulley through its centre of gravity, respectively, both being expressed in gravitation units. Assuming, therefore, certain values for c/l and c/k, tables have been drawn up giving the corresponding values of θ. For each value of c/l there are two limiting values of c/k; viz., *infinity* and *zero*—the corresponding values of k being *zero* and *infinity*. When $k = 0$ the pulley may be considered simply as a dead weight, so that the "inferior period of whirl," as it has been termed, is the natural period of vibration of the light shaft under the given conditions. The "superior period of whirl," that is to say, the whirling period when $k = \infty$ is the inferior period multiplied by some function of c/l, and assuming the shaft to whirl at a speed corresponding to the superior or inferior limit, it would do so in such a manner that the pulley still rotated in a plane perpendicular to the original alignment of the shaft. These limiting values of the speed, below and above which whirling is impossible, have been calculated in each case.

Investigation shows that in a continuous light shaft supported on bearings placed at equal distances apart, the increase in the whirling speed due to those spans which are not immediately adjacent to the loaded one, on either side, cannot exceed by above 2 or 3 per cent. the whirling speed when only the loaded span and the spans immediately adjacent to it are taken into account. In other words, the stiffening effects of only those spans immediately adjacent to the loaded one, on either side, need be taken into account in calculating the whirling speed for the shaft.

By substituting the proper values for the constants in Equation (4) we obtain the equations

$$\mathrm{N} = \phi\,d^2/\sqrt{\mathrm{W}\,c^3}, \text{ for a solid shaft,} \quad \ldots \ldots \quad (5)$$

and

$$= \phi\,\sqrt{(d_1^4 - d_2^4)}/\sqrt{\mathrm{W}\,c^3}, \text{ for a hollow shaft,} \quad . \quad (6)$$

where W, d, d_1, d_2 have the same values as before, and ϕ is some numerical coefficient depending on the value of θ and of the constants in Equation (4).

The value of ϕ for wrought-iron or mild steel is $5389\,\theta$, and for brass $3772\,\theta$.

Having thus obtained formulæ giving the whirling speed due to each cause, on the assumption that all the others are neglected, it only remains to find an empirical formula giving the resulting whirling speed, when all the disturbing elements are taken into account, in terms of the separately-calculated whirling speeds due to the several causes. Since the whirling speed in every case varies inversely as the square root of the weight of the pulley (*see* Equation 4), the formula for calculating the resulting speed was to be of the form

$$\mathrm{N}_1\,\mathrm{N}_2/\sqrt{(\mathrm{N}_1^2 + \mathrm{N}_2^2)} \quad \ldots \ldots \quad (7)$$

for two disturbing elements whose whirling speeds taken separately are N_1, N_2; or of

$$\mathrm{N}_1\mathrm{N}_2\mathrm{N}_3/\sqrt{(\mathrm{N}_2^2\mathrm{N}_3^2 + \mathrm{N}_3^2\mathrm{N}_1^2 + \mathrm{N}_1^2\mathrm{N}_2^2)}, \quad \ldots \quad (8)$$

for three disturbing elements whose whirling speeds, taken separately, are N_1, N_2, N_3. The formula may be extended to any number of disturbing elements. It is not strictly accurate, for in addition to the whirling speed varying inversely as the square root of the weight of the pulley, it also varies as some function (θ) of the distance of the pulley from the nearest bearing and of the size of the pulley. The experiments, however, justify to a remarkable degree the assumptions that have been made in calculating the resulting whirling speed.

In calculating the speed at which a continuous shaft of given diameter, supported on bearings placed at equal distances apart, and loaded with pulleys on any or all of the spans, will whirl, the method to adopt is to first find the span which will have the biggest whirl (that is to say, the span which carries the heaviest and most advantageously-placed pulleys as regards whirling), and then to consider this span and the spans immediately adjacent on either side. The whirling speeds for the shaft and each of the pulleys on the three spans have then to be calculated according to the rules laid down in each case. The whirling speed for any pulleys on the two side spans will, of course, be different according as that side span is an end or an intermediate span in the line of shafting. Having found the whirling speed due to each cause, the resulting whirling speed is found from an equation of the same form as Equation (7) or (8)—the exact equation depending on the number of disturbing elements. The speed thus obtained will be slightly less than the actual whirling speed. A nearer approximation to the actual speed might be obtained by considering only those pulleys which lie near the centres, or between the centres of the side spans and the bearings of the middle span, neglecting the effect of those pulleys which lie beyond the centres of the side spans. In doing so, however, the experiments show that there is a danger of the calculated speed *exceeding* the actual, whilst by taking *all* the pulleys on the two side spans into account the calculated speed will be slightly *less* than the actual speed.

If the spans of a continuous shaft, supported on bearings placed at equal distances apart, are all loaded in the same manner, each whirls independently of the rest, and the problem reduces to that of a loaded shaft supported on bearings at the ends.

The experimental shaft was 2ft. 8in. long and ·2488in. in diameter. The motion was transmitted from the headstock spindle to the experimental shaft by a fine piece of steel wire (about 1½in. long and 21 B.W.G. diam.), so that the shaft was subjected to very little constraint at the end. The experimental pulleys were models of actual pulleys—being designed for both weight and inertia. The headstock spindle was driven from a turbine, the constancy of the speed being shown by the steadiness of a column of liquid forced by a centrifugal fan indicator up a glass tube. In taking the number of revolutions corresponding to any period of whirl an ordinary counter pushed into the end of the headstock spindle was used. In making any experiment three trials were made (each of three minutes' duration) and the mean of the results taken. Over 150 experiments have been made with this apparatus, and the observed results invariably approximate very closely to the calculated results. Experiments have also been made with actual cases of shafting, and it would appear that, following the method of solution sketched above, the calculated speed is about 3 or 4 per cent. *less* than the actual speed.

The experiments were carried out in the Whitworth Engineering Laboratory, Owens College, Manchester.

LEGAL INTELLIGENCE.

Re Woodhouse and Rawson United (Limited).

PUBLIC EXAMINATION OF DIRECTORS.

In the Bankruptcy Court on Monday, before Mr. Registrar Hood, the public examination was commenced of the Directors of Woodhouse and Rawson United (Limited). The examination was conducted by the Official Receiver, Mr. C. J. Stewart, and various parties were represented as follows:—Mr. Jenkins, instructed by Mr. Frederic Walker, represented Sir John Stokes and Mr. Samuel Pope, Q.C.; Mr. Eve and Mr. Mossop, instructed by Messrs. Travers, Smith and Co., represented Mr. Philip Rawson; Mr. Muir Mackenzie and Mr. Geake, instructed by Messrs. Lees and Pemberton, represented Lord Aberdare; Mr. Kartnell represented Mr. C. L. Baker; and Mr. Pilling, of Manchester, appeared for creditors.

The OFFICIAL RECEIVER said before the examination commenced he wished to state that the investigation had been a very difficult one, and he had met with especial difficulty in ascertaining the facts prior to the examination before his Honour, owing to the absence of a large number of original documents. The Directors and officers of the Company had been communicated with with respect to these, but without success. There were also books, particularly the minute book of Woodhouse and Rawson (Limited) acquired by Woodhouse and Rawson United under agreement, which, in spite of repeated applications to the liquidators of Woodhouse and Rawson (Limited) and to the officers of Woodhouse and Rawson United, he had been unable to obtain. He suggested that he should first of all put the liquidators of Woodhouse and Rawson (Limited) in the box and ask them where those books were, as he was unable otherwise to obtain any information.

The REGISTRAR assented to this course, and

Sir JOHN STOKES was called and examined by the Official Receiver. He said he was a Director of Woodhouse and Rawson (Limited), and subsequently became a liquidator. He had forwarded to the Official Receiver a letter he had received from Mr. Richard regarding the books in question, in which it was stated that the books had been ordered to be destroyed. That order was given as the result of a resolution passed at the final meeting of the shareholders in November last, the winding-up order of the United Company having been made on May 17, 1893. So far as he recollected, the order was given by himself as chairman.

The OFFICIAL RECEIVER: You knew an inquiry was on the eve of taking place in the United Company, and you were informed, I think, of the Receiver's observations. Under those circumstances you, I understand, proposed that these books, which must be very material to the United Company, should be destroyed?—We did not take the view that they were very material to the United Company. We had no reason to suppose so; we had never been asked for them.—Not at that date, but subsequently you were?—Subsequently; within the last few days. Can you speak from your own knowledge as to whether the minute-book has or has not been destroyed?—I cannot.

Examined by Mr. Jenkins: He had been applied to by the Official Receiver with regard to certain points, and had given information to the best of his power. He was requested to obtain information from Mr. Richard, who had had charge of the books, and the result was the letter which he had sent to the Official Receiver. That request was made in a personal interview recently, and no reference to the books was made in the letters he had received from the Official Receiver asking for information. He presided at the final dissolution meeting of Woodhouse and Rawson (Limited), and so far as his memory went there was a general resolution approving what had been done, and ordering the destruction of the books. That was put from the chair in the ordinary way and carried. No reason was suggested at that time why the books, of which there were a large number, should not be destroyed.

In reply to the Official Receiver, the WITNESS said if the minute-book had not been destroyed and it could be found, he would see that it should be produced.

Mr. FREDERICK L. RAWSON was next called, and, in reply to the Official Receiver, said he could throw no light upon the whereabouts of the minute-book. He had told Mr. Richard that all the books in his possession would be wanted, and asked him to keep them and bring them up when called upon. He understood afterwards that he had no books. He had nothing to do with destroying the books, and he was surprised to learn that they had been destroyed. He had no recollection of having been present at the meeting when the resolution referred to was passed. He would undertake that the minute book should be produced if it had not been destroyed.

Sir ALBERT J. LEPPOC CAPPEL, K.C.I.E., was then examined. He was one of the original Directors of Woodhouse and Rawson United, but retired on August 1, 1889, before the Company went to allotment. He was first approached by Mr. F. L. Rawson, who came to him with an introduction from a friend. He was not acquainted with any of the Directors at the time he joined the Board. He could only give a general impression, after so many years, of the representations made to him by Mr. Rawson. He understood that there were four excellent industrial undertakings, which for reasons of general policy and economy it was desirable to combine into one. These were—Woodhouse and Rawson (Limited), the Woodhouse and Rawson Electric Supply Company, the Woodhouse and Rawson Manufacturing Company, and the Woodhouse and Rawson Contract and Maintenance Company, and there was also C. L. Baker and Company (Limited), which it was proposed to take in.

The OFFICIAL RECEIVER: Did Mr. Rawson mention to you that there was any other branch which they were going to undertake except the industrial business?—Well, yes; he did say that by fostering patents there would be a good deal of money made. That is to say, men who were clever, but suffered from lack of introductions, and especially from want of means, would be helped by the knowledge and the money, primarily the money, of this combination.

Continuing, WITNESS said he certainly regarded it as mainly an industrial business. From what was told him the impression on his mind was that these were all profitable concerns, except, he thought, one of the small ones, which was not in quite so good a position, but which, when absorbed, would not be in any way detrimental. He did not remember whether that was the Manufacturing Company. There were several meetings prior to the incorporation of the Company on July 12, 1889, but no formal record was kept, and no resolutions were passed. He was present at most of those, but he could not recall all the steps that were taken or all the questions put to ascertain the value of the businesses which it was proposed that the new Company to be formed should purchase. He himself drew up a memorandum of points upon which information was required, and those points were dealt with. He did not recollect whether at that time he had seen the valuation of the patents made by Mr. Henry Edmunds.

The OFFICIAL RECEIVER read the document referred to, in which Mr. Edmunds referred to the fact that, although the patents held by the Woodhouse and Rawson Company were of considerable value, they had not realised a profit in working during the last few years; but it was to be borne in mind that the Company had been passing through a trying period, that very few electrical companies had made any money at all, but were building up their businesses in order to prepare for the large increase in electrical work which was anticipated. Reference was also made to the incandescent lamp patent litigation, in which the Company had been engaged. Great stress was laid upon the value of the licence held from the British Electric Light Company, which enabled them to manufacture under the Edison incandescent lamp patent.

WITNESS said he had seen this document, but he could not tell now what he understood to be the valuation put upon the patents by Mr. Edmunds. The £159,265 referred to in the document appeared to be built up of various sums; but it represented the idea in his mind of what the patents were valued at. He would like to state that these things took place a long time ago, and the matter not being a pleasant one he tried to dismiss it from his mind, so that he had some difficulty in taking up isolated facts connected with it, and he did not think he could do more than give a general impression of his recollections.

WITNESS, continuing, in reply to the Official Receiver, said he had seen a list of patents with the valuation by Mr. Edmunds, in which the total value was put at £159,265. Woodhouse and Rawson (Limited), paid the expenses of the promotion. He understood the valuation referred to in the prospectus was an independent one.

The OFFICIAL RECEIVER: Were you aware that this valuation was actually drafted by Mr. F. L. Rawson?—Certainly not.

Had you known that I take it you would have looked with—I don't say suspicion, but you would have thought Mr. Rawson, being in the position of vendor, would entertain rather an exaggerated idea of the value of what he was going to sell?—If I had had this knowledge I think I should have left the place there and then.

Did you understand that in this valuation the Elmore patents were to be included or whether they were not to be included?—I find a short note of mine, made for my own guidance in attending the meeting, to this effect: "Mr. Budd to explain with reference to patent valuation whether the needful information has been supplied by Mr. Rawson in a form which appears to him satisfactory." Then I find another note which shows that there was a deduction on account of the Elmore patents.

That looked, then, as if the Elmore patents were not included?—Certainly, I think so.

Mr. Edmunds is asked with regard to the Elmore patents, and he says: "I assented to the value given to me by Mr. Rawson in conversation." He further said, Mr. Rawson had very big ideas as to the value of the Elmore patents, and the witness considered that the things of great value were the Elmore patents and the lamps. Mr. Rawson gave him the idea, in conversation, that the Elmore patents were worth about £200,000. Were you aware that in that valuation Mr. Edmunds valued the Elmore patents, which apparently were not included in the patents taken over by the United Company, at somewhere about £120,000?—I had no knowledge at all of the valuation of the Elmore patents.

Did you understand that the Limited Company, or one of these companies, had taken over a licence from the British Electric Light Company?—I think I remember there was a licence, which was possessed for manufacturing incandescent lamps, and that great value was attached to it. I do not think I can go further that.

Are you aware that there was no power by which the Electric Light Company could transfer this licence? Did you become aware of that?—Never, that I remember.

May I take it that you were thoroughly satisfied as to the possession of these patents?—I think we were.

Had you any assurance from the solicitors that the patents were all in order?—That I do not know. We had a solicitor always present, advising us in every step we took.

You were giving a very large amount for these patents—£85,000. Supposing you were buying these as a private person, and they were offered you for £85,000?—Of course, one would endeavour to assure oneself that they were worth it.

I want to know what steps you took?—I do not remember.

After hearing that evidence (of Mr. Edmunds), would you have agreed to purchase those patents for £85,000?—Certainly not.

The price to be paid for these five businesses was £269,000, and that appears to be, for the stock £29,000, plant £10,500, patents £85,500, freehold property £47,000, and goodwill £97,000. What was your idea of good-will?—I believed that this was a successful industrial undertaking, which had a valuable connection, and that it was a business which, with proper business-like arrangement and care, would prove very valuable.

Digitized by Google

Proceeding, WITNESS said it was represented to him that the profits of the business of Woodhouse and Rawson (Limited) for the year ending June 30, 1888, were £21,440, and that the profits for the following year were estimated at over £75,000. That was stated in the prospectus. It was a fair assumption that it was on those statements he based his idea of the value of the goodwill. It was stated that the profits were partly represented by shares in other companies, and the explanation given was that it was by no means uncommon for profits made in that way to be included.

The OFFICIAL RECEIVER read a special report of the auditors, Messrs. Pixley, giving details of the items of profit arising from the assumed value of interests acquired in other companies, and explaining that the realisation of the values given depended upon certain contingencies.

WITNESS had no recollection of having heard that report read, and did not think he would have been satisfied with the statement in the prospectus if he had read it or heard it read. He went and saw the works in the case of some of the businesses to be acquired. He was under the impression that Woodhouse and Rawson (Limited) was a small company in the sense that the shares were not very largely distributed, but he did not know that the shares were held almost entirely by Mr. Rawson and his friends.

You had not had much experience of companies? —I had had none then.

These negotiations apparently all went through in the course of about a month?—The thing was very much rushed. It was at a rather later period that he got this feeling that the matter was being rushed. He began to feel uneasy, and, in conjunction with Col. Howard Vincent and Sir John Coode, he was determined that the Company should not go to allotment unless the applications for shares reached a certain amount. They objected to some of the applications on the ground that they were not of a very substantial character. It was strictly because the amount which they had decided upon as a minimum had not been subscribed that he retired from the Board, but he must confess he was much relieved at that opportunity presenting itself to enable him to withdraw. When the first feeling of uneasiness arose he began to look into matters more, and he was much dissatisfied with the want of order and exactness with which everything was done. A meeting of the Directors was held on July 30th, and as the total applications were not sufficient to produce £200,000 a resolution was passed deciding not to proceed to allotment. Immediately after that decision he was "fired at" by several legal gentlemen, representing the several businesses to be acquired, who said they should hold him liable for expenses and damages. These letters were all couched in pretty much the same language. On August 1st there was another meeting of the Board, and after an adjournment it was agreed that those letters should be withdrawn, that the resolution of July 30th should not be immediately acted upon, and that a circular should be addressed to the applicants informing them that Sir Albert Cappell, Sir John Coode, and Col. Howard Vincent had withdrawn from the Board. He was anxious that if anybody had been attracted by his name appearing on the prospectus he should have the opportunity of withdrawing. A circular was sent out, but it was not quite satisfactory to him or in accordance with the resolution. For one thing, the applicants were not specifically informed that it was open to them to withdraw their applications. Lord Aberdare and Mr. Philip Rawson were the other provisional Directors, but it only came to his knowledge afterwards that himself, Col. Howard Vincent, and Sir John Coode were the only Directors who were not interested as vendors.

Examined by Mr. EVE on behalf of Mr. Philip Rawson, witness said they were advised throughout by a solicitor, and they went through the prospectus very carefully. He could not say whether they had also the advice of counsel. He did not remember the opinion of Mr. Buckley being obtained as to the way in which the profits of Woodhouse and Rawson (Limited) were to be dealt with, nor did he recollect that some new arrangement was made with regard to the £75,000 profits as a consequence of the opinion obtained.

He did not know that the circular alluded to was sent out on August 2nd, the Friday before Bank Holiday, and that the allotment was fixed for the day after Bank Holiday; and if that were the case he did not consider that it was a sufficient compliance with his desire that applicants should have an opportunity of withdrawing upon learning of his retirement.

By Mr. F. L. RAWSON: He did not recollect that it was at first contemplated not to include Woodhouse and Rawson (Limited) amongst the other companies to be acquired; but to have an Electrical Union, consisting more especially of the manufacturing companies. He did not recollect that, after some discussion, the Directors of Woodhouse and Rawson (Limited), having objected to the transfer of that Company in consequence of the delays that had taken place, it was agreed that that Company should be taken over as from June, 1889, if the £75,000 profits were lodged as a guarantee fund, and if, in addition, the United Company gave up their share in the Elmore patents, and he (Mr. Rawson) also gave up his share in those patents. He remembered that he (Mr. Rawson) did on more than one occasion talk about and explain from his point of view the value of the lamp patents; but he (witness) did not himself make any report, even a verbal report, to the Board regarding the lamps, as he had no knowledge which would justify him in doing so. With regard to what he had said about matters being rushed, he had no recollection of Mr. Rawson having told him that the thing must be settled before the Bank Holiday, or else it would have to be put off until the autumn. He believed Col. Howard Vincent raised an objection to the application of the Secretary, who applied for 200 shares. He did not recollect whether there were any other objections. His point was that they had not a sufficient subscription to satisfy their scruples. He recollected being told that Mr. Philip Rawson was not a relative or a connection in any way of Mr. Frederick Rawson. There were several drafts made of the prospectus before the final one—certainly over a dozen. The Directors had numerous meetings, and he personally took a great deal of trouble in the matter, but he could not remember the details of all that took place. He went carefully into the agreements, and insisted upon several alterations being made in them to suit his views. He did not recollect that the Foreign Elmore Company in June, 1889, purchased from Woodhouse and Rawson (Limited) their interest in the Elmore patents. He did not know anything of the circumstances under which Mr. Edmunds's valuation was made; that he came to town suddenly, and, not having his shorthand writer with him, asked him (Mr. Rawson) to have a shorthand writer in the room so that he could dictate his report, he (Mr. Rawson) commenting upon some matters as they arose to see that he got his facts right. He did not recollect that the £159,000 was arrived at by deducting the amount of the value of the foreign Elmore patent from the total amount of Mr. Edmunds's valuation. He certainly considered that if a lamp could be manufactured on royalty for 1s. 2d., and the selling price was 3s. 6d., the patent for that would be of considerable value, especially if he knew such a lamp fetched 6d. and 1s. more than other lamps in the trade. He did not know that some thousands of pounds were returned in consequence of the issue of the circular prior to the allotment.

By Mr. PILLING: He did not remember whether the balance-sheets of any of the companies to be acquired were shown to him or not. Sir John Stokes and other Directors of Woodhouse and Rawson (Limited), as well as Mr. F. L. Rawson, were sometimes present at the meetings. Mr. Rawson represented the selling Company. He knew that that gentleman was to be managing Director of the new Company, but not that he was to receive a large sum of money for promoting the Company. The more he went into the matter the less he liked it.

WITNESS, in response to the invitation of the Registrar to make any statement he might wish to make, said he took what he thought at the time was a good deal of pains to look into the matter, and as time went on he gradually found that it wanted more looking into. At all events, there was wanted an amount of supervision and control on the part of the new Directors which it would be almost impossible to exercise, and his desire was, when he resigned, that anybody who might have been attracted by his name in the prospectus should have an opportunity of knowing that he had retired. That object he thought he had secured by insisting upon the issue of the circular.

Col. HOWARD VINCENT, M.P., was the next witness, and, examined by the Official Receiver, said he was first approached by Mr. F. L. Rawson to become a Director of the United Company, which he understood was to be entirely an industrial concern. He had no idea that company promotion was to be one of the features. He knew a certain amount of the profits referred to of Woodhouse and Rawson (Limited) was in shares. He went into the thing rather later than the other Directors, and put in £5,000, and in making inquiries to make up leeway, he soon began to be suspicious and to think that the Company had been promoted in a very unbusinesslike manner; the minutes were not properly kept, and he had difficulty in obtaining accurate and exact information. In regard to the valuation of the patents and other matters, he put a good deal of confidence in the knowledge of Sir John Coode, who was President of the Institution of Civil Engineers. He thought he must have read the report of Mr. Pixley, the auditor, dated May 7, 1889. He was dissatisfied as to the manner in which the £21,440 profit in Woodhouse and Rawson (Limited) had been earned when he saw the report, and therefore required a personal explanation from the auditor; but was satisfied with the personal explanation, the character of which he could not remember. He understood that the profits for the then current year, 1889, were no less than £75,000, which amount was available in cash, and would be held in reserve for a few years. The persons applying for shares would probably have been put on their guard had they read the passage in the auditor's report, which said, "the accounts are in accordance with the books of the Company, but it is obviously impossible for us to be responsible for the net profit, having regard to the nature of the assets of the Company's interest in many trading concerns not yet fully developed, and without Stock Exchange quotations of their shares." The statement in the prospectus without the paragraph quoted, did not, he thought it very likely, give the shareholders the effect of the audit. With regard to the patents, he remembered that a great deal of value was put on the lamp. He remembered Mr. Rawson telling him that the partnership of Woodhouse and Rawson and the subsequent limited Company had been very successful. He would not say whether he was made aware that the bulk of the profits of 1889, £78,000, was made by a successful Stock Exchange transaction in Elmore shares; he knew he was very anxious to have the £75,000 deposited in cash. He thought the amount given for the goodwill of Woodhouse and Rawson (Limited), £75,000, was a good deal too much. He could not remember being told that the assets of that Company included a debt of £37,000 due from the Manufacturing Company. He knew he was exceedingly anxious that they should not proceed further until they had been to Manchester to see the works purchased there, but, as Sir Albert Cappell had said, the matter was hurried on a good deal and he was borne away. His impression was that the suggestion that they should not go to allotment unless £200,000 was available in cash was made by him.

By Mr. MUIR MACKENZIE (on behalf of Lord Aberdare): No doubt there were valuations of the actual assets in the component companies put before the provisional Directors; he did not recollect the details, but was quite sure they gained all the information they could. They took considerable pains to investigate the properties proposed to be purchased, but he thought now they ought to have taken more; they were, however, much pressed, as it was said the season was going on. His reason for retiring was that not sufficient capital was subscribed, added to the unbusinesslike character of the promotion. He thought they had been unduly hurried, and that the Managing Director would want more control than he would have time to give him.

By Mr. EVE: The only reason given at the time of his resignation was the insufficiency of capital; his other reasons were scarcely sufficiently definite to be given. They may have been imaginary, but they certainly existed in his mind. There was a certain reluctance in giving information,

Digitized by Google

the papers were not sufficiently in order, the minutes were not sufficiently carefully kept, and so on.

Mr. F. L. RAWSON asked if it was not the fact that he was examined at considerable length as to the profits of Woodhouse and Rawson (Limited).—Witness replied that he (Mr. Rawson) was present at all the meetings, and he desired the presence of Mr. Pixley, the auditor, to confirm what was said. Up to the date of his retirement there had been nothing of a speculative or Stock Exchange character in the transactions of the Company; had there been, he should have withdrawn at once. Looking at the matter from a distance of five years, he thought they ought to have had more detailed information than they did; but it was difficult to suggest anything more that the Directors could have done that they did not do.

Mr. RAWSON: Have you ever heard it suggested that I ever had a penny for the promotion of Woodhouse and Rawson United?—It would not be credited that you would work for nothing.

Mr. RAWSON: As a matter of fact I did, but it has been stated that I had received a large amount for the promotion.

WITNESS, in conclusion, said he would confirm what Sir Albert Cappell had said that they went very carefully into the facts as far as they could in the limited time at their disposal. They were pressed not to quibble too much, as it was absolutely necessary to proceed at once if the Company was to be formed. When sufficient money was not provided they withdrew, and considered that that step would lead all sensible people to conclude that they did not approve of something in connection with the Company.

Further examination was adjourned until the following day.

TUESDAY, JUNE 19TH.

The first witness was Mr. C. L. BAKER, who stated, in reply to the Official Receiver, that he formerly acted as managing director of C. L. Baker and Co. (Limited), which was a Company subsequently acquired by Woodhouse and Rawson United (Limited). About the beginning of 1889 the question of amalgamation with Woodhouse and Rawson was brought before his Directors and shareholders, and, it being pointed out that unless they agreed to the scheme their Company would have to encounter very serious opposition, they agreed to the proposition. It was said that all the other companies concerned in the scheme were doing good business. He would not say that the Directors of C. L. Baker and Co. (Limited), understood that a large proportion of the proposed Company's business would consist of financial work or company promoting. It was known, however, that patents relating to electrical work would be "fostered." He was not aware of the sums to be paid for the other businesses acquired, but he knew that only an exceedingly small cash payment was to be made. C. L. Baker and Co. (Limited) received in all £24,000 for their business, being as to £5,000 in cash, and £19,000 in Preference shares, the amount for goodwill being £9,000, which was represented by *bonâ-fide* profitable contracts. Independent valuations were made of the plant and stock, and he was of opinion that they were under-valued. He saw the prospectus before it was issued, in which it was stated that the profits of Woodhouse and Rawson (Limited) for the year ending June 30, 1888, amounted to £21,440. He was not aware, however, that the auditors submitted a report to the effect that "the accounts are in accordance with the books of the Company, but it is obviously impossible for us to be responsible for the net profit, owing to the nature of the assets and the Company's interest in many trading concerns." Mr. F. L. Rawson assured him that great care had been exercised in the preparation of the prospectus, and he understood that every statement contained in it was correct. He was subsequently informed that a difficulty had been raised about going to allotment, owing to three of the Directors being dissatisfied with the amount of capital subscribed. He thereupon pointed out that if, from this cause, the Company did not go to allotment most serious injury would be inflicted upon C. L. Baker and Co. (Limited), as this Company had specially stipulated that they should not be dangled before the public as a bait, and he therefore instructed his solicitor to acquaint the Directors of the United Company with his intention to proceed against them for damages if they declined to go to allotment. The Company, however, went to allotment, and witness was appointed general works manager at Cadby Hall, Kensington, and Cornbrook telegraph works, Manchester. He had had considerable experience in managing works of this kind, having been for a great number of years an electrical engineer. Shortly after the Company was started he became aware that a sum of £85,000 had been paid for the patents acquired by the Company.

By the OFFICIAL RECEIVER: At the time he thought they might have been worth from £30,000 to £50,000; but now they were practically worthless, there being only one or two which were workable, but this was owing, to a great extent, to their being superseded by other inventions.

The OFFICIAL RECEIVER: I believe the industrial branch of the Company's business has been a failure throughout its existence, has it not?—WITNESS said that very heavy losses had been incurred, but he attributed this to the fact that the business had been cut up and distributed, instead of being carried on under the management of one person. He did not think the losses in question amounted to £50,000. The foundry at Kidsgrove, Staffordshire, was purchased by the Company for £30,000, in shares. It was represented that the business carried on there was producing £8,000 a year profit, and, thinking that they were acting in the interest of the shareholders, the Directors decided to acquire it. As a matter of fact it had shown a considerable loss, and the Directors estimated that the property had depreciated to the extent of £17,784 in July, 1892. When he entered upon his duties at Cadby Hall he experienced a considerable amount of difficulty in ascertaining anything about the concern, and to a great extent he was regarded as an interloper. Upon inquiry he discovered that affairs were in a very unsatisfactory condition, and upon his representing the same to the Directors they expressed some surprise, and Sir John Stokes said he was disgusted with the state of things. In April, 1892, he sent a letter to each of the Directors calling their attention to the position of matters, and suggesting certain alterations; but no action was taken upon it, and no mention of the matter was made to him. His only explanation of this was that the Board must have been engaged on more important business at the time. Ultimately he was unable to obtain funds for the purpose of carrying on the works, and a large proportion of the experienced hands were dismissed. In his opinion there had not been sufficient funds provided from the commencement, and difficulties had been experienced throughout. Shares to the value of £2,000 were given to him as his interest in C. L. Baker and Co. (Limited); but at the date of the winding-up order he did not hold any of them, because he knew too much about the concern. He had realised from £3. 12s. down to 3s. 6d. for a £5 share. He had also purchased other shares in the Company when his faith in it increased, but these had also been disposed of.

By Mr. MUIR MACKENZIE: When the business of C. L. Baker and Co. (Limited) was transferred to the united company he believed it was in a flourishing condition, and capable of realising a large profit. When he joined the United Company he had every reason to believe that with good management it would have been a prosperous company.

In reply to Mr. F. L. Rawson, WITNESS stated that he had never heard it suggested that the latter had ever acted in a manner which was other than straightforward.

By a CREDITOR: At the time C. L. Baker and Co. (Limited) was transferred it was a profitable concern; but it was impossible to say whether that particular branch had been so or not since the amalgamation, as the various businesses had been merged into one, and they could not be separated.

Further examined by Mr. BUTCHER: The Directors of C. L. Baker and Co. (Limited) were never anxious to amalgamate with the other companies; but, in view of the opposition which they would have to face, it was considered advisable to do so. The names of responsible gentlemen appearing on the prospectus inspired him with confidence in the concern.

It was stated at this point of the inquiry that the minute-book of Woodhouse and Rawson (Limited), which it was supposed had been lost or destroyed, had been found, and was at the disposal of the Official Receiver.

Mr. F. W. PIXLEY was next examined, and, in reply to the Official Receiver, stated that he had acted as auditor of Woodhouse and Rawson United (Limited) and of the Woodhouse and Rawson Electric Supply Company (Limited). Being on one occasion unable to obtain the necessary materials for the purpose of auditing the accounts of the latter company, his firm threatened to take further steps in the matter. He could not say whether that particular audit had ever been completed. In the prospectus of the Company it was stated that a profit of £21,000 had been made by Woodhouse and Rawson (Limited) in the previous year, but he did not certify to those profits—that was a matter which rested entirely with the Directors. His certificate as auditor was accompanied by a report to the shareholders, and the certificate and the report ought to have been read together. In a book which he had written on the subject he expressed the opinion that the auditor's report ought to accompany the accounts which were issued to shareholders. He had since had occasion to modify that opinion owing to the difficulty of enforcing what he, as an auditor, might consider to be proper, and the book now quoted from was a very early edition of his work. As auditor for the shareholders he considered it was his function to see that the transactions and accounts were as represented by the Directors, and that there was nothing wrong about them at all; but he was in no sense a "watch-dog." As to the duty of an auditor, he might say that on one occasion he took upon himself to enlighten the shareholders, and the only acknowledgement he got for his trouble was his dismissal, because he was said to have exceeded his powers.

The OFFICIAL RECEIVER: If you thought that it would be better for the shareholders not to know something, do you consider that you are justified in not telling them?—WITNESS: Yes, subject to certain qualifications.

Mr. REGISTRAR HOOD: What are they?

WITNESS said that there were numbers of trading companies now in existence in which it would be very disastrous for the public to know full particulars of their business transactions.

At this point the inquiry was adjourned.

WEDNESDAY, JUNE 20TH.

Mr. F. W. PIXLEY, the auditor, was again examined by the Official Receiver. He said he recollected that large sums were paid by the United Company into the International Okonite Company, in which application was made for shares to a large extent. A profit was stated to have been made of £17,000 on the Kensington Stores transaction, this being the sale of the front part of the Cadby Hall premises to the Kensington Stores, a company promoted by the United Company. He questioned the right to include this as a profit of the year, and counsel's opinion was taken at his request. He had no opportunity of putting his views before counsel, and he could not say that he ever saw the case put.
